Abstract

This paper studies the synchronization problem of a new chaotic four-Dimensional System presented by Qi et al. Two different methods, passive control method and impulsive control method are used to control synchronization of the four-dimensional chaotic system. Numerical simulations show the effectiveness of the two different methods.

Keywords: Qi Four-dimensional chaotic system, Chaotic synchronization, Passive control. Impulsive control.

1. Introduction

In 1963, Lorenz found the first a chaotic attractor in a simple three-dimensional autonomous system (Sparrow, 1982). Later, an even simpler three-dimensional chaotic system, which has only one cross-product term, was constructed by Rössler (Rössler, 1976). In 1999, Chen and Ueta presented another well-known three-dimensional chaotic system (Chen et al., 1999), referred to as Chen system that has been proved to be dual and topologically nonequivalent to Lorenz system. Whereafter, Lü system (Lü et al., 2002), a critical system between Lorenz and Chen system, was constructed in 2002, followed by the Lorenz system family (Lü et al., 2003) as a connection of Lorenz, Chen and Lü systems; so far, there are many researchers who

studied the chaos theory (Wu et al. , 2007).

During the last decades dynamic chaos theory has been deeply studied and applied to many fields extensively, such as secure communications, optical system, biology and so forth (Sun, 2004).

Recently, (Qi et al. , 2005) constructed a new 4D autonomous chaotic system, which has cubic cross-product nonlinearity in each equation. This system can generate complex dynamics within wide parameters ranges, including chaos, Hopf bifurcation, perioddoubling bifurcation, periodic orbit, sink and source, and so on (Qi et al. , 2006).

The problem of chaos synchronization is directly related to the observer problem in control theory. In general, the designed controller with the state variable of the master will make the trajectories of the state variables of the slave system to track the trajectories of the state variables of the driver system (Vincent et al. , 2008).

Until now, many different techniques and methods have been proposed to achieve chaos synchronization, such as OGY method (Lai et al. , 1993), linear feed-back method (Han et al. , 2004), adaptive synchronization method (Liao et al. , 1998), backstepping nonlinear control method (Tan et al. , 2003), sliding mode control method (Shimizu et al. , 2005), active control (Vincent et al. , 2008) and projective synchronization method (liu et al. , 2007).

In the present paper, the passive control and impulsive control methods are applied to synchronize two identical new chaotic four-Dimensional System presented by Qi et al. Numerical simulations show the effectiveness of the two different methods.

2. System description

We consider the new 4D chaotic system to be synchronized described by (Qi et al. , 2005):

$$\begin{cases} \dot{x}_1 = a(x_2 - x_1) + x_2x_3x_4 \\ \dot{x}_2 = b(x_1 + x_2) - x_1x_3x_4 \\ \dot{x}_3 = -cx_3 + x_1x_2x_4 \\ \dot{x}_4 = -dx_4 + x_1x_2x_3 \end{cases}$$

where $c = c_1 + c_2 \sin(t)$, and a, b, c_1, c_2, d are all positive real constant parameters. The dynamics of this system has been extensively investigated by Qi et al. For a fixed subset of the system parameters with autonomous case

$c_2 = 0$ and non-autonomous case $c_2 \neq 0$. The dependence of the bifurcation diagrams and the Lyapunov exponent that were a function of the parameter d were presented. In particular, the 4D system exhibits chaotic behavior for the following parameters:

Case I: autonomous case

$a = 35, b = 10, c_1 = 1, c_2 = 0, d = 10$.

Case II: non-autonomous case

$a = 30, b = 10, c_1 = 95, c_2 = 10, d = 10$.

Figures 1 and 2 shows the chaotic attractor of the system for case I and case II.

Figure 1: Views of the chaotic attractor of the system: case I

3. Synchronization of the 4D chaotic system

3.1. Passive control method

Some preliminaries of passivity theory used in this paper will be shortly reviewed for the consistency of the presentation. Passivity is applied to non-linear systems which are modelled by ordinary differential equations with

Figure 2: Views of the chaotic attractor of the system: case II

input vector $u(t)$ and output vector $y(t)$ (Yu, 1999) and (Kemih et al. , 2007):

$$\begin{cases} \dot{x}(t) = f(x(t), u(t)) \\ y(t) = h(x(t)) \end{cases} \quad (1)$$

The system (1) is dissipative with the supply rate $W(u(t), y(t))$ if it is not able to generate power by itself, that is the energy stored in the system is less than or equal to the supplied power:

$$V(x(t)) \geq 0 \quad \text{and} \quad V(x(T)) - V(x(0)) \leq \int_0^T W(u(t), y(t)) dt \quad (2)$$

Furthermore, the storage function $V(x(t))$ must satisfy the requirements for a Lyapunov function. If there exist a positive semi definite Lyapunov function, such that:

$$\int u^T(\tau)y(\tau)d\tau \geq \int \left[\frac{\partial V(x(\tau))}{\partial x(\tau)} f(x\tau), u(\tau) + eu^T + \delta y^T(\tau)y(\tau) + \rho\Phi(x(\tau)) \right] d\tau \quad (3)$$

The system (1) is passive. A passive system implies that any increase in storage energy is due solely to an external power supply. Then the equilibrium point of the system:

$$\dot{x} = f(t, x(t), 0) \quad (4)$$

is asymptotically stable in either of the two cases:

- $\rho > 0$
- $e + \delta > 0$ and the system is zeros-state observation.

The system (1) can be represented as the normal form:

$$\begin{cases} \dot{z} = f(z) + g(z, y)y \\ \dot{y} = l(z, y) + k(z, y)u \end{cases} \quad (5)$$

The nonlinear system (5) may be rendered bay a state feedback of the form (Yu, 1999):

$$u = \alpha(z, y) + \beta(z)v \quad (6)$$

The dynamical system is described as:

$$\begin{cases} \dot{x}_1 = a(x_2 - x_1) + x_2x_3x_4 \\ \dot{x}_2 = b(x_1 + x_2) - x_1x_3x_4 \\ \dot{x}_3 = -cx_3 + x_1x_2x_4 \\ \dot{x}_4 = -dx_4 + x_1x_2x_3 \end{cases} \quad (7)$$

While the response system can be described as:

$$\begin{cases} \dot{y}_1 = a(y_2 - y_1) + y_2y_3y_4 \\ \dot{y}_2 = b(y_1 + y_2) - y_1y_3y_4 + u \\ \dot{y}_3 = -cy_3 + y_1y_2y_4 \\ \dot{y}_4 = -dy_4 + y_1y_2y_3 \end{cases} \quad (8)$$

Now define the error states are: $e_1 = y_1 - x_1$, $e_2 = y_2 - x_2$, $e_3 = y_3 - x_3$ and $e_4 = y_4 - x_4$, so the dynamics of the error system is determined as following:

$$\begin{cases} \dot{e}_1 = a(e_2 - e_1) + y_2y_3y_4 - x_2x_3x_4 \\ \dot{e}_2 = b(e_1 + e_2) - y_1y_3y_4 + x_1x_3x_4 + u \\ \dot{e}_3 = -ce_3 + y_1y_2y_4 - x_1x_2x_4 \\ \dot{e}_4 = -de_4 + y_1y_2y_3 - x_1x_2x_3 \end{cases} \quad (9)$$

Let system (9) is already in the normal form of (5), where: $z_1 = e_1$, $z_2 = e_3$, $z_3 = e_4$, $y = e_2$, $z = [z_1, z_2, z_3]^T$,

$$f(z) = [-az_1 + y_2y_3y_4 - x_2x_3x_4, -cz_2 + y_1y_2y_4 - x_1x_2x_4, -dz_3 + y_1y_2y_3 - x_1x_2x_3]^T,$$

$$g(z, y) = [a, 0, 0]^T, \quad l(z, y) = bz_1 + by - y_1y_3y_4 + x_1x_3x_4, \quad k(z, y) = 1 \quad (10)$$

Our object is to design a smooth control (6) for the $4D$ chaotic system to make the closed-loop system passive. Choose a storage function candidate:

$$V(z, y) = W(z) + \frac{1}{2}y^2 \quad (11)$$

where $W(z)$ is Lyapunov function with $W(0) = 0$,

$$W(z) = \frac{1}{2}(z_1^2 + z_2^2 + z_3^2) \quad (12)$$

The zero dynamics of the system (9) describes those internal dynamics which are consistent with external constraint $y = 0$, i.e.,

$$\dot{z} = f(z) \quad (13)$$

Consider (13):

$$\begin{aligned} \frac{d}{dt}W(z) &= [z_1 \quad z_2 \quad z_3]f(z) \\ &= (-az_1 + y_2y_3y_4 - x_2x_3x_4)z_1 + (-cz_2 + y_1y_2y_4 - x_1x_2x_4)z_2 \\ &\quad + (-dz_3 + y_1y_2y_3 - x_1x_2x_3)z_3 \leq 0 \end{aligned} \quad (14)$$

The zero dynamics of error synchronization system is Lyapunov stable. The derivative of $V(z, y)$ along the trajectory of the $4D$ chaotic system (9) is:

$$\begin{aligned} \frac{d}{dt}V(z, y) &= \frac{\partial}{\partial z}W(z)\dot{z} + y\dot{y} \\ &= \frac{\partial}{\partial z}W(z)f(z) + \frac{\partial}{\partial z}W(z)g(z, y)y + l(z, y)y + k(z, y)uy \end{aligned} \quad (15)$$

The error system is minimum phase:

$$\frac{d}{dt}W(z)f(z) \leq 0 \quad (16)$$

Equation (15) becomes:

$$\frac{d}{dt}V(z, y) \leq \frac{\partial}{\partial z}W(z)g(z, y)y + (l(z, y) + k(z, y)u)y \quad (17)$$

If we select the feedback control (6) of the following form and consider (9):

$$\begin{aligned} u &= k^{-1}(z, y)[-l^T(z, y) - \frac{\partial W}{\partial z}g(z, y) - \gamma y + v] \\ &= -(a + b)z_1 - (b + \gamma)y + y_1y_2y_3 - x_1x_2x_3 + v \end{aligned} \quad (18)$$

where γ is positive constant and v is an external signal which is connected with the reference input. The above inequality can be rewritten as:

$$\frac{d}{dt}V(z, y) \leq -\gamma y^2 + vy \quad (19)$$

Then integrating both side of (19)

$$V(z, y) - V(z_0, y_0) \leq \int_0^t -\gamma y(\tau)^2 d\tau + \int_0^t v(\tau)y(\tau) d\tau \quad (20)$$

$V(z, y) \geq 0$ and $\rho = V(z_0, y_0)$

$$\int_0^t v(\tau)y(\tau) d\tau + \rho \geq V(z, y) + \int_0^t -\gamma y(\tau)^2 d\tau \geq \int_0^t -\gamma y(\tau)^2 d\tau \quad (21)$$

It satisfies the passive definition (3). The 4D chaotic system (9) is rendered to be output strict passive (OSP) under the feedback control.

3.2. Impulsive control method

We decompose the linear and nonlinear parts of the four-dimensional system in Eq.(9) and rewrite it as :

$$\dot{e} = Ae + \Phi(e) \quad (22)$$

where:

$$e = (e_1, e_2, e_3, e_4)^T, A = \begin{bmatrix} -a & a & 0 & 0 \\ b & b & 0 & 0 \\ 0 & 0 & -c & 0 \\ 0 & 0 & 0 & -d \end{bmatrix}$$

and

$$\Phi(e) = \begin{bmatrix} y_2 y_3 y_4 - x_2 x_3 x_4 \\ -y_1 y_3 y_4 + x_1 x_3 x_4 \\ y_1 y_2 y_4 - x_1 x_2 x_4 \\ y_1 y_2 y_3 - x_1 x_2 x_3 \end{bmatrix} \quad (23)$$

Then, the impulsive control of the critical system is given by (Zhang et al. , 2007):

$$\begin{cases} \dot{E} & = AE + \Phi(e), t \neq t_i \\ \Delta E & = BE, t = t_i, i = 1, 2, \dots \\ e(t_0^+) & = e_0 \end{cases} \quad (24)$$

Note that there exists a positive constant M for the chaotic system (7) that $| (x(t))^2 | \leq M$ for all t .

Where t_i denotes the instant when impulsive control occurs. For convenience, define the following notation:

$$\lambda_2(A) = \frac{1}{2} \lambda_{\max}(A + A^T), \beta_i = \lambda_{\max}[(I + B_i)^T(I + B_i)] \quad (25)$$

Where I is the $n \times n$ identity matrices, and $\lambda_{\max}(A)$ is the maximal eigenvalue of matrices A .

Theorem 1. 1. If $2\lambda_2(A) + 2M = \lambda < 0$ (λ is a constant) and there exists a constant $0 \leq \alpha < -\lambda$, such that

$$\ln \beta_i - \alpha(t_i - t_{i-1}) \leq 0, k = 1, 2, \dots \quad (26)$$

Then the trivial solution of system (9) is globally exponentially stable.

2. If $2\lambda_2(A) + 2M = \lambda \geq 0$ (λ is a constant) and there exists a constant $\alpha \geq 1$, such that

$$\ln(\alpha\beta_i) + \lambda(t_{i+1} - t_i) \leq 0, k = 1, 2, \dots \quad (27)$$

Then $\alpha = 1$ implies that the trivial solution of system (9) is stable and $\alpha > 1$ implies that the trivial solution of system (9) is globally asymptotically stable.

Proof 1. Let the Lyapunov function be in the form of: $v(e) = e^T e$
The time derivative of $V(e)$ along with the solution of Eq.(9) is :

$$\begin{aligned}
\dot{V}(e) &= \dot{e}^T e + e^T \dot{e} = (Ae + \Phi)^T e + e^T (Ae + \Phi) \\
&= e^T (A^T + A)e + \Phi^T e + e^T \Phi \\
&= e^T (A^T + A)e + 2(2e_1 e_3 x_2 x_4 - e_1 e_2 e_4 x_3 - 3e_1 e_3 e_4 x_2 - e_2 e_3 e_4 x_1 \\
&\quad - e_1 e_2 e_3 x_4 + 2e_1 e_4 x_2 x_3 + 2e_3 e_4 x_1 x_2 - 2e_1 x_2 x_3 x_4 + 2e_2 x_1 x_3 x_4 \\
&\quad - 2e_3 x_1 x_2 x_4 - 2e_4 x_1 x_2 x_3 + 2e_1 e_2 e_3 e_4) \\
&\leq 2(\lambda_2(A) + 8M)v(e(t)), t \in (t_{i-1}, t_i], i = 1, 2, \dots
\end{aligned} \tag{28}$$

Which implies that:

$$V(e(t)) \leq V(e(t_{i-1}^+)) \exp(2(\lambda_2(A) + 8M)(t - t_{i-1})), t \in (t_{i-1}, t_i], i = 1, 2, \dots \tag{29}$$

On the other hand, it follows from system (10) that

$$\begin{aligned}
V(t_i^+) &= ([I + B_i]e(t_i))^T ([I + B_i]e(t_i)) \\
&\leq \beta_i V(e(t_i)), i = 1, 2, \dots
\end{aligned} \tag{30}$$

The following results come from (14) and (15). For $t \in (t_0, t_1]$

$$V(e(t)) \leq V(e(t_0^+)) \exp(2(\lambda_2(A) + 8M)(t - t_0)) \tag{31}$$

which leads to

$$V(e(t_1)) \leq V(e(t_0^+)) \exp(2(\lambda_2(A) + 8M)(t_1 - t_0)) \tag{32}$$

$$\begin{aligned}
V(t_1^+) &\leq \beta_1 V(e(t_1)) \\
\text{and : } &\leq \beta_1 V(e(t_0^+)) \exp(2(\lambda_2(A) + 8M)(t_1 - t_0))
\end{aligned} \tag{33}$$

Therefore, for $t \in (t_1, t_2]$

$$\begin{aligned}
V(e(t)) &\leq V(e(t_1^+)) \exp(2(\lambda_2(A) + 8M)(t - t_1)) \\
&\leq \beta_1 V(e(t_0)) \exp(2(\lambda_2(A) + 8M)(t - t_0))
\end{aligned} \tag{34}$$

In general, for $t \in (t_i, t_{i+1}]$

$$V(e(t)) \leq V(e(t_0^+)) \beta_1 \beta_2 \dots \beta_i \exp(2(\lambda_2(A) + 8M)(t - t_0)) \tag{35}$$

1. When $2\lambda_2(A) + 2M = \lambda < 0$, it follows from (12) and (20) that for $t \in (t_i, t_{i+1}]$

$$\begin{aligned} & V(e(t_0^+))\beta_1\beta_2\dots\beta_i \exp(2(\lambda_2(A) + 8M)(t - t_0)) \\ & \quad = V(e(t_0^+))\beta_1\beta_2\dots\beta_i \exp(\lambda(t - t_0)) \\ & = V(e(t_0^+))\beta_1\beta_2\dots\beta_i \exp(-\alpha(t - t_0)) \exp((\alpha + \lambda)(t - t_0)) \end{aligned}$$

Then:

$$\begin{aligned} V(e(t)) & \leq V(e(t_0^+))\beta_1\beta_2\dots\beta_i \exp(-\alpha(t_i - t_0)) \exp((\alpha + \lambda)(t - t_0)) \\ & \leq V(e(t_0^+)) \exp((\alpha + \lambda)(t - t_0)) \end{aligned} \quad (36)$$

Which implies that the trivial solution of Eq.(9) is globally asymptotically stable.

2. When $2\lambda_2(A) + 2M = \lambda \geq 0$, it follows from (13) and (20) that for $t \in (t_i, t_{i+1}]$

$$\begin{aligned} V(e(t)) & \leq V(e(t_0^+))\beta_1\beta_2\dots\beta_i \exp(2(\lambda_2(A) + 8M)(t - t_0)) \\ & \leq V(e(t_0^+))\beta_1\beta_2\dots\beta_i \exp(\lambda(t_{i+1} - t_0)) \\ & \leq V(e(t_0^+))\beta_1 \exp(\lambda(t_1 - t_0))\beta_2 \exp(\lambda(t_3 - t_2))\dots \\ & \quad \beta_i \exp(\lambda(t_{i+1} - t_i)) \exp(\lambda(t_1 - t_0)) \\ & \leq V(e(t_0^+)) \frac{1}{\alpha^i} \exp(\lambda(t_1 - t_0)) \end{aligned} \quad (37)$$

In practice, for the seek of convenience, the gain matrices B_i are often selected as a constant matrix and the impulsive distances $\tau_i = t_i - t_{i-1}$ ($i = 1, 2, \dots$) are set to be a positive constant. Then we have the following corollary.

Corollary 1. Assume $\tau_i = \tau > 0$ and matrices $B_i = B$, ($i = 1, 2, \dots$)

1. If $2\lambda_2(A) + 2M = \lambda < 0$ (λ is a constant) and there exists a constant $0 \leq \alpha < -\lambda$, such that $\ln \beta_i - \alpha\tau \leq 0$, then the trivial solution of system (9) is globally exponentially stable.
2. If $2\lambda_2(A) + 2M = \lambda \geq 0$ (λ is a constant) and there exists a constant $\alpha \geq 1$, such that $\ln(\alpha\beta_i) + \lambda\alpha\tau \leq 0$.

4. Numerical simulation

In this section, numerical simulations are given to verify the proposed methods. In these numerical simulations, the fourth-order Runge-Kutta method is applied to solve the differential equations with time step size equal to 0.01 in all numerical simulations. Selected the initial values of the dynamical system (7) are $x_1(0) = 1, x_2(0) = 1, x_3(0) = 1, x_4(0) = 1$ and the initial values of the response system (8) are $y_1(0) = -1, y_2(0) = -5, y_3(0) = 1, y_4(0) = 1$. We select $\gamma = 11$ and use the controller as in (18). Figures 3 and 4 shows the state time response of the dynamical system (7) and the response system (8) with the passive method for the two case. Here, the dot line stands for the track of the dynamical system and the solid line stands for the track of the response system. The error state of the dynamical system (7) and the response system (8) converges to the zero.

For the impulsive control method, we have $A + A^T = \begin{pmatrix} 70 & 45 & 0 & 0 \\ 45 & 20 & 0 & 0 \\ 0 & 0 & -2 & 0 \\ 0 & 0 & 0 & -20 \end{pmatrix}$

Its eigenvalues are -20.00, -6.48, -2.00 and 96.48, then $2\lambda_2(A) + 2M = \lambda = 96.48 + 800 > 0$.

If we choose the gain matrices $B_i, (i = 1, 2, \dots)$ as a constant matrix $B = \text{diag}(b_1, b_2, b_3) = (-0.30, -0.40, -0.50, -0.60)$, then it is easy to see that: $\beta = \max\{(1 + b_1)^2, (1 + b_2)^2, (1 + b_3)^2\} = 0.49$ Then estimates of bounds of stable regions are given by $0 \leq \tau \leq \frac{\ln \alpha + \ln(0.49)}{896.48}$. Take $\alpha = 1.01$, then $0 \leq \tau \leq 0.0011$.

We choose $\tau = 0.0009$. Figures 5 and 6 shows the state time response of the dynamical system (7) and the response system (8) with the impulsive method for the two cases. Here, the dot line stands for the track of the dynamical system and the solid line stands for the track of the response system. The error state of the dynamical system (7) and the response system (8) converges to the zero.

5. Conclusion

This paper studies the synchronization problem of two identical chaotic four-Dimensional System presented by Qi et al. based on the Lyapunov stability theory and the impulsive control technology, the authors get the suf-
