## Numerical Accuracy Evaluation for Polynomial Computation

Jean-Charles Naud<sup>\*†</sup>, Daniel Ménard<sup>‡†</sup>

Project-Teams CAIRN

Research Report n° 7878 — February 2012 — 17 pages

**Abstract:** Fixed-point conversion requires fast analytical methods to evaluate the accuracy degradation due to quantization noises. Usually, analytical methods do not consider the correlation between quantization noises. Correlation between quantization noises occurs when a data is quantized several times. This report explained, through an example, the methodology used in the ID.Fix tool to support correlation. To decrease the complexity, a method to group together several quantization noises inside a same noise source is described. The maximal relative estimation error obtained with the proposed approach is less than 2%.

**Key-words:** fixed-point, quantization, analytic approach, noise, correlation

## Évaluation de la précision numérique pour calcul polynomial

**Résumé :** La conversion en virgule fixe nécessite des méthodes analytiques rapides pour évaluer la dégradation de la précision liée aux bruits de quantification. Actuellement, les méthodes analytiques ne considèrent pas la corrélation entre les bruits de quantification. Cette corrélation est due à la quantification d'une même donnée plusieurs fois. Ce rapport explique, au travers d'un exemple, la méthodologie utilisée dans l'outil ID.Fix pour prendre en compte la corrélation. Pour diminuer la complexité, une méthode de regroupement des bruits de quantification dans une source de bruit est décrite. La valeur maximale de l'erreur d'estimation relative obtenue avec l'approche proposée est inférieure à 2%.

**Mots-clés :** virgule fixe, quantification, approche analytique, corrélation

## 1 Introduction

Fixed-point arithmetic is widely used in embedded systems to reduce implementation costs like execution time, area and power consumption. Fixed-point conversion is composed of two main steps corresponding to dynamic range evaluation and word-length (WL) optimization. The aim of WL optimization is to minimize the implementation cost as long as the effects of finite precision are acceptable. This optimization process is based on an iterative procedure where the numerical accuracy is evaluated a great number of times. Thus, efficient methods are required to evaluate this numerical accuracy to limit the optimization time.

To evaluate numerical accuracy, approaches based on fixed-point simulations are generic, but they also lead to long execution times. Thus, the search space is drastically limited and sub-optimal solutions are obtained. Analytic methods reduce significantly the evaluation time by providing the mathematical expression of a metric equivalent to the numerical accuracy. The output quantization noise power is widely used as a relevant metric for evaluating the numerical accuracy.

Usually, analytical methods do not consider the correlation between quantization noises. Correlation between quantization noises occurs when a data is quantized several times. In this report, the expressions of the correlation and the covariance, considering the number of eliminated bits, are presented for truncation and rounding. Then, this report explained, through an example, the methodology used in the ID.Fix tool to support correlation.

## 2 Methodology description

### Problem description

Correlation between QNSs occurs when a data  $x_0$  is quantized several times. Figure 1 shows such an example where  $x_i$  is the data after each quantization  $Q_i$  with  $i$  equal to 1 or 2.  $Q_i$  leads to an unavoidable quantization error  $e_i$  between the values of the data  $x_i$  and  $x_0$ .  $e_i$  can be assimilated to a noise source and we denote  $E_i$  as the random variable corresponding to this error. Let  $w_i$  denote the fractional part word-length of the data  $x_i$  and  $q_i$  the quantization step associated to  $x_i$ .  $q_i = 2^{-w_i}$  with  $w_i$  the weight of the least significant bit. The number of bits eliminated during the quantization process  $Q_i$  is defined as  $k_i$ . The relation between the quantization step  $q_i$  and  $q_0$  is  $q_i = 2^{k_i} q_0$ , with  $i$  equal to 1 or 2. If  $x_0$  is in infinite precision  $q_0$  is equal to zero and  $k_1$  and  $k_2$  tend to infinity. Let  $X_i$  denote the set containing all the values that can be represented in the fixed-point format after the quantization  $Q_i$ .

Given that  $k_2$  bits are common between the QNSs  $e_1$  and  $e_2$ , these QNSs are correlated. Let  $y$  denote the output of the global targeted system. Let  $H_i$  denote the system having  $e_i$  as input and  $y$  as output. As the QNS  $e_i$  propagates through the system  $H_i$ , correlation between different QNSs  $e_i$  obviously influences the output noise power and has therefore to be considered for a precise numerical accuracy evaluation.

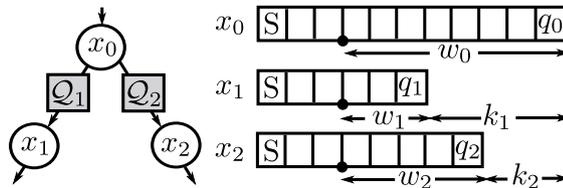

Figure 1: Quantized data representation

## 2.1 Quantization Mode Description

In this section, the probability density function and the statistical moments of the QNSs generated during a quantization process are presented for the truncation and rounding quantization modes in the case of two's complement coding. The quantization process  $\mathcal{Q}_1$  presented in Figure 1 is under consideration. The quantization error  $e_1$  resulting from the quantization process  $\mathcal{Q}_1$  is defined as

$$e_1 = x_0 - x_1. \quad (1)$$

By using Widrow's model [1, 2],  $e_1$  can be assimilated to an additive white noise, uniformly distributed, which is uncorrelated to the signal.

### 2.1.1 Truncation

In the case of truncation, the data  $x_0$  is always rounded towards the lower value available in the set  $X_1$  and becomes

$$x_1 = \lfloor x_0 \cdot q_1^{-1} \rfloor \cdot q_1 = t \cdot q_1 \quad \forall x_0 \in [t \cdot q_1, (t+1) \cdot q_1[ \quad (2)$$

with  $\lfloor \cdot \rfloor$  the floor function defined as  $\lfloor x_0 \rfloor = \max(n \in \mathbb{Z} | n \leq x_0)$  and with  $q_1$  the quantization step. The probability density function (PDF) of the QNS  $p_{E_1}(e_1)$  is given by (3) with  $\delta$  the Kronecker delta.

$$p_{E_1}(e_1) = \frac{1}{2^{k_1}} \sum_{j=0}^{2^{k_1}-1} \delta(e_1 - j \cdot q_0) \quad (3)$$

### 2.1.2 Rounding

Rounding quantization mode rounds the value  $x_0$  to the nearest value available in the set  $X_1$  as

$$x_1 = \left\lfloor \left( x_0 + \frac{1}{2} q_1 \right) \cdot q_1^{-1} \right\rfloor \cdot q_1. \quad (4)$$

The midpoint  $q_m = (t + \frac{1}{2}) \cdot q_1$  between  $t \cdot q_1$  and  $(t+1) \cdot q_1$  is always rounded up to the higher value  $(t+1) \cdot q_1$ . For this quantization mode, the PDF  $p_{E_1}(e_1)$  is given by

$$p_{E_1}(e_1) = \frac{1}{2^{k_1}} \sum_{j=-2^{k_1-1}}^{2^{k_1-1}-1} \delta(e_1 - j \cdot q_0). \quad (5)$$

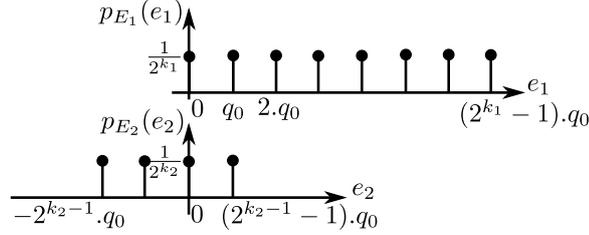

From [3] and [4], mean and variance expressions are given in Table 1 for each quantization mode  $\mathcal{Q}_1$ . If  $x_0$  has a continuous amplitude, as in analog-to-digital conversion,  $k_1$  is considered as  $+\infty$ .

## 2.2 Correlation and covariance expressions

In this section, the expressions of the correlation and the covariance between two QNSs  $e_1$  and  $e_2$ , resulting from the quantization of one unique data  $x_0$  as presented in Figure 1, are determined. The covariance is used in the expression of the global output quantization noise power to improve the quality of the noise power estimation. The reasoning to determine the correlation and covariance expressions is detailed in the following with  $k_1 \geq k_2$  and for the case

Table 1: Mean and variance for the two quantization modes

Quantization mode $Q_1$	Mean	Variance
Truncation	$\frac{q_1}{2} \cdot (1 - 2^{-k_1})$	$\frac{q_1^2}{12} \cdot (1 - 2^{-2k_1})$
Rounding	$-\frac{q_1}{2} \cdot (2^{-k_1})$	$\frac{q_1^2}{12} \cdot (1 - 2^{-2k_1})$

Figure 2: PDF of the QNSs  $e_1$  and  $e_2$  for  $Q_1 = T$ ,  $Q_2 = R$ ,  $k_1 = 3$  and  $k_2 = 2$ .  $q_0$  is the quantization step.

where  $Q_1$  is a truncation (T) and  $Q_2$  a rounding (R). The two discrete PDFs  $p_{E_1}$  and  $p_{E_2}$  of respectively the QNSs  $e_1$  and  $e_2$  are presented in Figure 2 for the case of  $k_1 = 3$  and  $k_2 = 2$ .

Let  $E_1$  and  $E_2$  denote the discrete random variables corresponding to the QNSs. The correlation  $E[E_1 \cdot E_2]$  is determined from  $p_{E_1, E_2}$  the joint probability density function between  $E_1$  and  $E_2$  as

$$E[E_1 \cdot E_2] = \sum_i \sum_j i \cdot q_0 \cdot j \cdot q_0 \cdot p_{E_1, E_2}(e_1 = i \cdot q_0, e_2 = j \cdot q_0) \quad (6)$$

where  $i$  and  $j$  enumerate the possible events of  $e_1$  and  $e_2$ .

The joint probability density function  $p_{E_1, E_2}$  is obtained from  $p_{E_1|E_2}$  the conditional probability of  $E_1$  given  $E_2$  as

$$p_{E_1, E_2}(e_1, e_2) = p_{E_1|E_2}(e_1|e_2) \cdot p_{E_2}(e_2), \quad (7)$$

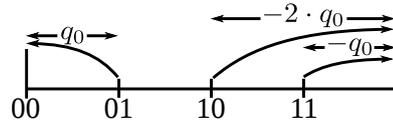

For each value of  $e_2$ ,  $2^{k_1 - k_2}$  values are obtained for  $e_1$ , thus

$$p_{E_1|E_2} = \frac{1}{2^{k_1 - k_2}} \cdot \left[ \sum_{j=0}^{2^{k_2-1}-1} \delta(e_2 - j q_0) \sum_{t=0}^{2^{k_1-k_2}-1} \delta(e_1 - e_2 - t \cdot q_2) \right. \\ \left. + \sum_{j=-2^{k_2-1}}^{-1} \delta(e_2 - j q_0) \sum_{t=0}^{2^{k_1-k_2}-1} \delta(e_1 - e_2 - (t+1) \cdot q_2) \right] \quad (8)$$

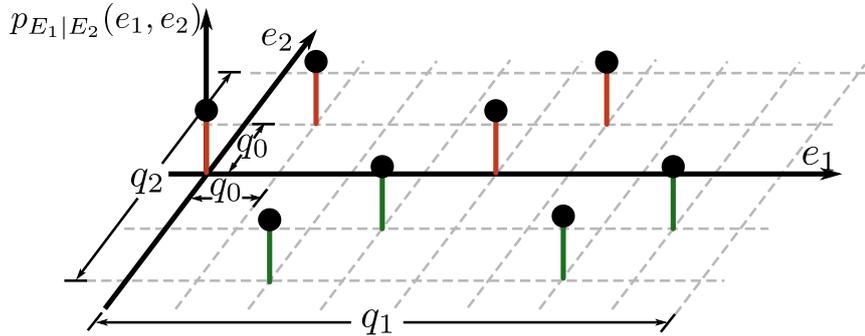

To illustrate equation 8, the example with  $k_1 = 3$  and  $k_2 = 2$  is considered. Thus, the different cases for the quantization error  $e_1$  and  $e_2$  are provided in Table 2.

The columns bit 2, bit 1 and bit 0 specify the three LSB of the quantized data ( $x_0$ ). The weight of the bit 0 is  $q_0$ . In our case,  $e_2$  is due to the elimination of 2 bits with rounding quantization mode. The figure 3 presents the different values of the error  $e_2$ .

bit 2	bit 1	bit 0	$e_1$	$e_2$
0	0	0	0	0
0	0	1	$q_0$	$q_0$
0	1	0	$2q_0$	$-2q_0$
0	1	1	$3q_0$	$-q_0$
1	0	0	$4q_0$	0
1	0	1	$5q_0$	$q_0$
1	1	0	$6q_0$	$-2q_0$
1	1	1	$7q_0$	$-q_0$

 Table 2: Values of the eliminated bits during the quantization and associated error  $e_1$  and  $e_2$ .

 Figure 3: Different values of the error  $e_2$  for the rounding quantization with  $k_2 = 2$ 

The result is shown in Figure 4. Red Dirac and green Dirac correspond respectively to the first part (two first summations) and the second part (two last summations) of the previous expression. The amplitude of the different Dirac are the same and equal to  $\frac{1}{2^{k_1-k_2}}$ .

 Figure 4: Joint probability  $p_{E_1|E_2}(e_1, e_2)$ 

From eq. 7 and 6, the correlation between  $E_1$  and  $E_2$  becomes

$$\begin{aligned}
 \mathbb{E}[E_1 \cdot E_2] &= \frac{q_0^2}{2^{k_1}} \sum_{t=0}^{2^{k_1-k_2}-1} \sum_{j=0}^{2^{k_2-1}-1} j(j+t \cdot 2^{k_2}) \\
 &+ (j - 2^{k_2-1})(j + 2^{k_2-1} + t \cdot 2^{k_2}) \\
 &= -\frac{q_2^2}{24} + \frac{q_0^2}{6} - \frac{q_0 \cdot q_1}{4}.
 \end{aligned} \tag{9}$$

The covariance  $\text{cov}(E_1, E_2)$  is determined from the correlation term  $\mathbb{E}[E_1 \cdot E_2]$  as

$$\text{cov}(E_1, E_2) = \mathbb{E}[E_1 \cdot E_2] - \mathbb{E}[E_1] \cdot \mathbb{E}[E_2]. \tag{10}$$

Table 3: Correlation and covariance expressions for the different quantization modes of truncation (T) or rounding (R), and for different conditions on  $k_1$  and  $k_2$

$Q_1$	$Q_2$	Condition	$E[E_1.E_2]$	$\text{cov}(E_1, E_2)$
T	T	$k_1 \geq k_2$	$\frac{q_2^2}{12} + \frac{q_0^2}{6} - \frac{q_0 \cdot q_2}{4} - \frac{q_0 \cdot q_1}{4} + \frac{q_1 \cdot q_2}{4}$	$\frac{q_2^2}{12} - \frac{q_0^2}{12}$
T	R	$k_1 \geq k_2$	$-\frac{q_2^2}{24} + \frac{q_0^2}{6} - \frac{q_0 \cdot q_1}{4}$	$-\frac{q_2^2}{24} - \frac{q_0^2}{12}$
R	T	$k_1 > k_2$	$\frac{q_2^2}{12} + \frac{q_0^2}{6} - \frac{q_0 \cdot q_2}{4}$	$\frac{q_2^2}{12} - \frac{q_0^2}{12}$
R	R	$k_1 = k_2$	$\frac{q_2^2}{12} + \frac{q_0^2}{6}$	$\frac{q_2^2}{12} - \frac{q_0^2}{12}$
R	R	$k_1 > k_2$	$-\frac{q_2^2}{24} + \frac{q_0^2}{6}$	$-\frac{q_2^2}{24} - \frac{q_0^2}{12}$

The term  $E[E_1].E[E_2]$  can be computed from the equations given in Table 1 and is equal to

$$\begin{aligned} E[E_1].E[E_2] &= \frac{q_1}{2} (1 - 2^{-k_1}) \frac{q_2}{2} (-2^{-k_2}) \\ &= \frac{q_0^2 - q_0 \cdot q_1}{4} \end{aligned} \quad (11)$$

Thus, from eq. 9 and 11, the expression of the covariance becomes

$$\text{cov}(E_1, E_2) = -\frac{q_2^2}{24} - \frac{q_0^2}{12} \quad (12)$$

Given that  $k_1 \geq k_2$ , the term  $q_1$  is eliminated because just the  $k_2$  least significant bits are common between  $e_1$  and  $e_2$ . The correlation and covariance expressions are given in Table 4 for the different quantization modes  $Q_i$  corresponding to truncation (T) or rounding (R) and for different conditions on  $k_1$  and  $k_2$ . If  $x_0$  is in infinite precision,  $q_0$  is equal to 0.

### 2.3 Output Quantization Noise Power

Different models have been proposed to estimate the power of the quantization noise at the output of a system [5, 6, 7, 8]. These approaches do not consider the correlation between quantization noises, but they can be easily extended to integrate this correlation to improve the estimation quality.

From [6], the output quantization noise  $e_y$  is the sum of the contributions of the  $N$  QNSs  $e_i$

$$e_y(n) = \sum_{i=1}^N \sum_{t=0}^{\infty} h_i(t, n) \cdot e_i(n-t) \quad (13)$$

where  $h_i$  corresponds to the time-varying impulse response of the system  $H_i$  between  $e_i$  and the output  $y$ . The term  $t$  represents the delay and  $n$  the time.

The power  $P_{e_y}$  of the output quantization noise is obtained by determining the second order moment of  $e_y$  with a similar derivation as in [6]. From (14), the expression of  $P_{e_y}$  is

$$P_{e_y} = E[E_y^2] = E \left[ \left( \sum_{i=1}^N \sum_{t=0}^{\infty} h_i(t, n) \cdot e_i(n-t) \right)^2 \right]$$

$$\begin{aligned}
 \mathbb{E} [E_y^2] &= \mathbb{E} \left[ \sum_{i=1}^N \sum_{j=1}^N \sum_{t=0}^{\infty} \sum_{v=0}^{\infty} h_i(t, n) \cdot h_j(v, n) \cdot e_i(n-t) \cdot e_j(n-v) \right] \\
 &= \mathbb{E} \left[ \sum_{i=1}^N \sum_{t=0}^{\infty} h_i^2(t, n) \cdot e_i^2(n-t) \right. \\
 &\quad + \sum_{i=1}^N \sum_{t=0}^{\infty} \sum_{\substack{v=0 \\ v \neq t}}^{\infty} h_i(t, n) \cdot h_i(v, n) \cdot e_i(n-t) \cdot e_i(n-v) \\
 &\quad + \sum_{i=1}^N \sum_{\substack{j=1 \\ j \neq i}}^N \sum_{t=0}^{\infty} h_i(t, n) \cdot h_j(t, n) \cdot e_i(n-t) \cdot e_j(n-t) \\
 &\quad \left. + \sum_{i=1}^N \sum_{\substack{j=1 \\ j \neq i}}^N \sum_{t=0}^{\infty} \sum_{\substack{v=0 \\ v \neq t}}^{\infty} h_i(t, n) \cdot h_j(v, n) \cdot e_i(n-t) \cdot e_j(n-v) \right] \quad (14)
 \end{aligned}$$

The different quantization noises  $e_i$  are assumed to be white so the autocorrelation is equal to

$$\mathbb{E}[e_i(n-t)e_i(n-v)] = \sigma_i^2 \delta(t-v) + \mu_i^2 \quad (15)$$

and the intercorrelation

$$\mathbb{E}[e_i(n-t)e_j(n-v)] = \text{cov}(E_i, E_j) \delta(t-v) + \mu_i \mu_j \quad (16)$$

$$\begin{aligned}
 \mathbb{E} [E_y^2] &= \sum_{i=1}^N \sum_{t=0}^{\infty} \mathbb{E} [h_i^2(t, n)] \cdot (\sigma_i^2 + \mu_i^2) \\
 &\quad + \sum_{i=1}^N \sum_{t=0}^{\infty} \sum_{\substack{v=0 \\ v \neq t}}^{\infty} \mathbb{E} [h_i(t, n) \cdot h_i(v, n)] \cdot \mu_i^2 \\
 &\quad + \sum_{i=1}^N \sum_{\substack{j=1 \\ j \neq i}}^N \sum_{t=0}^{\infty} \mathbb{E} [h_i(t, n) \cdot h_j(t, n)] \cdot (\mu_i \cdot \mu_j + \text{cov}(E_i, E_j)) \\
 &\quad + \sum_{i=1}^N \sum_{\substack{j=1 \\ j \neq i}}^N \sum_{t=0}^{\infty} \sum_{\substack{v=0 \\ v \neq t}}^{\infty} \mathbb{E} [h_i(t, n) \cdot h_j(v, n)] \cdot \mu_i \cdot \mu_j \quad (17)
 \end{aligned}$$

$$\begin{aligned}
 P_{e_y} = \mathbb{E} [E_y^2] &= \sum_{i=1}^N K_i \cdot \sigma_i^2 + \sum_{i=1}^N \sum_{j=1}^N L_{ij} \cdot \mu_i \cdot \mu_j \\
 &\quad + \sum_{i=1}^N \sum_{\substack{j=1 \\ j \neq i}}^N M_{ij} \cdot \text{cov}(E_i, E_j)
 \end{aligned}$$

with

$$\begin{aligned}
K_i &= \sum_{t=0}^{\infty} \mathbb{E} [h_i^2(t, n)], \\
L_{ij} &= \sum_{t=0}^{\infty} \sum_{v=0}^{\infty} \mathbb{E} [h_i(t, n)h_j(v, n)], \\
M_{ij} &= \sum_{t=0}^{\infty} \mathbb{E} [h_i(t, n)h_j(t, n)],
\end{aligned} \tag{18}$$

and where  $K_i$ ,  $L_{ij}$  and  $M_{ij}$  are constant terms depending only of the system in infinite precision, which can thus be determined only once. The variance  $\sigma_i^2$ , the mean  $\mu_i$  and the covariance  $\text{cov}(E_i, E_j)$  between QNSs depend on the quantization modes, the number of bit  $w_i$  for the fractional part and the number of bits eliminated  $k_i$  for each data  $x_i$ .

### 3 Application description

To illustrate the proposed approach, the computation of a  $3^{rd}$  order polynomial using the Horner scheme is presented. The Signal Flow Graph is presented in figure 5. The expression of the output  $y$  is

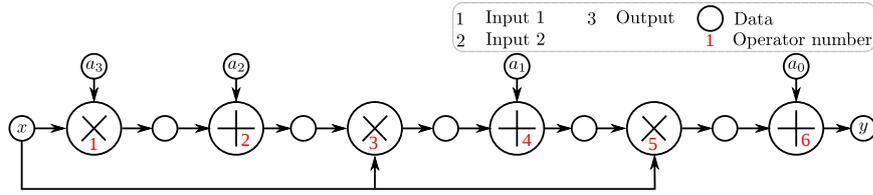

Figure 5:  $3^{rd}$  order polynomial using the Horner scheme

$$y(n) = a_0 + x(n).(a_1 + x(n).(a_2 + x(n).(a_3 + x(n)))) \tag{19}$$

#### 3.1 Quantizations noise modelling

A quantization noise is generated when the fractional word length ( $w_{FP}$ ) of a data is reduced. Each quantization error is modelled as a noise with the mean  $\mu$  and the variance  $\sigma$ . A quantization noise can be modelled with the quantization step  $q$ , the quantization mode ( $t_Q$ ) (truncation (T) or rounding (R)) and the number of eliminated bits  $k$  between the old and the new format.

#### 3.2 Noise source

The noise sources  $b$  allow grouping together different quantization noises  $e$  in the signal flow graph. Given that the complexity of the method depends on the number of quantization noise, the quantization noises are grouped together as much as possible to decrease the number of noise sources proceeded by the method.

The figure 6 shows, in the general case, the potential quantization noises (I, II, III, IV) associated with the noise source  $b$ . The  $w_{FP}$  of inputs and output of operation  $P_1$  are specified with  $w_{FP_{P_1,0}}$ ,  $w_{FP_{P_1,1}}$  and  $w_{FP_{P_1,2}}$ .

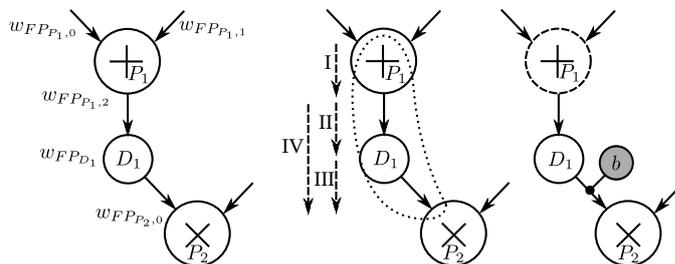

Figure 6: Quantization noise in a noise source

$P_i$  and  $D_i$  represent respectively the number associated to the operations and the data. Two cases are identified. In the first case, there is a word-length constraint  $w_{FPD_1}$  applied on data  $D_1$ . The quantization noises are I,II and III. In the second case, there is no restriction on  $w_{FPD_1}$ . In this case, only quantization noise I and IV are considered.

For the example of polynomial computation, the noise sources are inserted as show in figure 7.

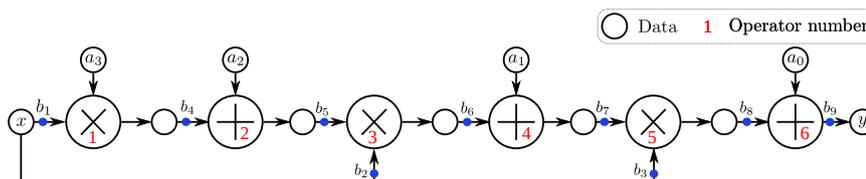

Figure 7: Noise sources insertion

### 3.3 Noise model propagation

The noise model propagation of each operator is inserted. An operation with two inputs  $x$  and  $y$  and the output  $z$  is considered. Let  $e_x$ ,  $e_y$  and  $e_z$  denotes the quantization noises associated with the input and the output. For the addition/subtraction, the output noise expression is :

$$e_z = e_x \pm e_y$$

For the multiplication, the output noise expression is :

$$e_z = e_x y \pm e_y x$$

Constant value are not considered to generate a quantization noise. By using previous expression, the noise data flow graph is generated as show in figure 8.

### 3.4 Determination of the impulse response of the system

Let  $H_i$  denote the system having the noise source  $b_i$  as input and  $y$  as output. Let  $h_i(t, n)$  denote the impulse response of  $H_i$ . The term  $t$  represents the delay and  $n$  the time. In our case, there is no delay, so  $h_i = 0, \forall t \neq 0$ .

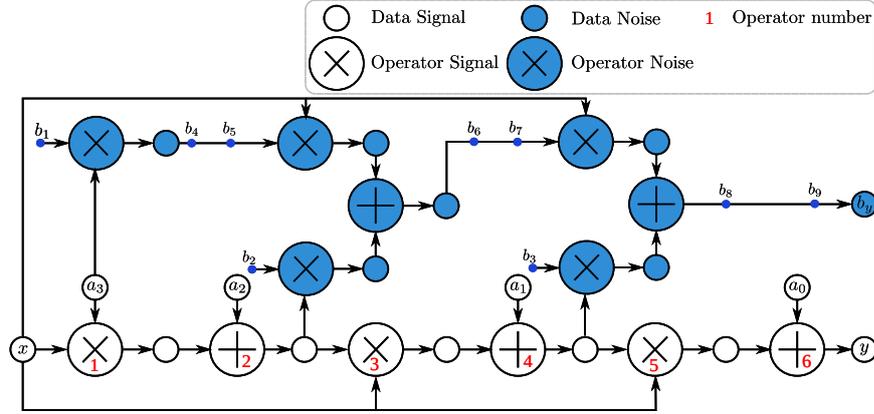

Figure 8: Noise models insertion

The expressions of the different impulse response  $h_i$  are :

$$\begin{aligned}
 h_1(0, n) &= a_3 * x^2(n) \\
 h_2(0, n) &= (a_3 * x(n) + a_2) \cdot x(n) \\
 h_3(0, n) &= (a_3 * x(n) + a_2) \cdot x(n) + a_1 \\
 h_4(0, n) &= x^2(n) \\
 h_5(0, n) &= x^2(n) \\
 h_6(0, n) &= x(n) \\
 h_7(0, n) &= x(n) \\
 h_8(0, n) &= 1 \\
 h_9(0, n) &= 1
 \end{aligned} \tag{20}$$

The matrices  $K$ ,  $L$  et  $M$  are computed only one time with the followers equations.

$$K_i = \sum_{t=0}^{\infty} \mathbb{E} [h_i^2(t, n)] \tag{21}$$

$$L_{ij} = \sum_{t=0}^{\infty} \sum_{v=0}^{\infty} \mathbb{E} [h_i(t, n) h_j(v, n)] \tag{22}$$

$$M_{ij} = \sum_{t=0}^{\infty} \mathbb{E} [h_i(t, n) h_j(t, n)] \tag{23}$$

The  $N$ -length vector  $K$  is equal to

$$\begin{pmatrix} \mathbb{E} [(a_3 * x^2(n))^2] \\ \mathbb{E} [((a_3 * x(n) + a_2) \cdot x(n))^2] \\ \mathbb{E} [((a_3 * x(n) + a_2) \cdot x(n) + a_1)^2] \\ \mathbb{E} [x^4(n)] \\ \mathbb{E} [x^4(n)] \\ \mathbb{E} [x^2(n)] \\ \mathbb{E} [x^2(n)] \\ 1 \\ 1 \end{pmatrix}$$

The different element of the  $N \times N$  matrix  $L$  are

$$\begin{aligned}
L_{11} &= \mathbb{E} [(a_3 * x^2(n))^2] \\
L_{12} = L_{21} &= \mathbb{E} [(a_3 * x^2(n)) \cdot ((a_3 * x(n) + a_2) \cdot x(n))] \\
L_{13} = L_{31} &= \mathbb{E} [(a_3 * x^2(n)) \cdot ((a_3 * x(n) + a_2) \cdot x(n) + a_1)] \\
L_{14} = L_{41} &= \mathbb{E} [(a_3 * x^2(n)) \cdot x^2(n)] \\
L_{15} = L_{51} &= \mathbb{E} [(a_3 * x^2(n)) \cdot x^2(n)] \\
L_{16} = L_{61} &= \mathbb{E} [(a_3 * x^2(n)) \cdot x(n)] \\
L_{17} = L_{71} &= \mathbb{E} [(a_3 * x^2(n)) \cdot x(n)] \\
L_{18} = L_{81} &= \mathbb{E} [a_3 * x^2(n)] \\
L_{19} = L_{91} &= \mathbb{E} [a_3 * x^2(n)] \\
\\
L_{22} &= \mathbb{E} [((a_3 * x(n) + a_2) \cdot x(n))^2] \\
L_{23} = L_{32} &= \mathbb{E} [((a_3 * x(n) + a_2) \cdot x(n)) \cdot ((a_3 * x(n) + a_2) \cdot x(n) + a_1)] \\
L_{24} = L_{42} &= \mathbb{E} [((a_3 * x(n) + a_2) \cdot x(n)) \cdot x^2(n)] \\
L_{25} = L_{52} &= \mathbb{E} [((a_3 * x(n) + a_2) \cdot x(n)) \cdot x^2(n)] \\
L_{26} = L_{62} &= \mathbb{E} [((a_3 * x(n) + a_2) \cdot x(n)) \cdot x(n)] \\
L_{27} = L_{72} &= \mathbb{E} [((a_3 * x(n) + a_2) \cdot x(n)) \cdot x(n)] \\
L_{28} = L_{82} &= \mathbb{E} [(a_3 * x(n) + a_2) \cdot x(n)] \\
L_{29} = L_{92} &= \mathbb{E} [(a_3 * x(n) + a_2) \cdot x(n)] \\
\\
L_{33} &= \mathbb{E} [((a_3 * x(n) + a_2) \cdot x(n) + a_1)^2] \\
L_{34} = L_{43} &= \mathbb{E} [((a_3 * x(n) + a_2) \cdot x(n) + a_1) \cdot x^2(n)] \\
L_{35} = L_{53} &= \mathbb{E} [((a_3 * x(n) + a_2) \cdot x(n) + a_1) \cdot x^2(n)] \\
L_{36} = L_{63} &= \mathbb{E} [((a_3 * x(n) + a_2) \cdot x(n) + a_1) \cdot x(n)] \\
L_{37} = L_{73} &= \mathbb{E} [((a_3 * x(n) + a_2) \cdot x(n) + a_1) \cdot x(n)] \\
L_{38} = L_{83} &= \mathbb{E} [(a_3 * x(n) + a_2) \cdot x(n) + a_1] \\
L_{39} = L_{93} &= \mathbb{E} [(a_3 * x(n) + a_2) \cdot x(n) + a_1] \\
\\
L_{44} &= \mathbb{E} [(x^2(n))^2] \\
L_{45} = L_{54} &= \mathbb{E} [(x^2(n))^2] \\
L_{46} = L_{64} &= \mathbb{E} [(x^2(n)) \cdot x(n)] \\
L_{47} = L_{74} &= \mathbb{E} [(x^2(n)) \cdot x(n)] \\
L_{48} = L_{84} &= \mathbb{E} [x^2(n)] \\
L_{49} = L_{94} &= \mathbb{E} [x^2(n)] \\
\\
L_{55} &= \mathbb{E} [(x^2(n))^2] \\
L_{56} = L_{54} &= \mathbb{E} [(x^2(n)) \cdot x(n)] \\
L_{57} = L_{75} &= \mathbb{E} [(x^2(n)) \cdot x(n)] \\
L_{58} = L_{85} &= \mathbb{E} [x^2(n)] \\
L_{59} = L_{95} &= \mathbb{E} [x^2(n)]
\end{aligned}$$

$$\begin{aligned}
L_{66} &= \mathbb{E}[x^2(n)] \\
L_{67} = L_{76} &= \mathbb{E}[x^2(n)] \\
L_{68} = L_{86} &= \mathbb{E}[x(n)] \\
L_{69} = L_{96} &= \mathbb{E}[x(n)] \\
\\
L_{77} &= \mathbb{E}[x^2(n)] \\
L_{78} = L_{87} &= \mathbb{E}[x(n)] \\
L_{79} = L_{97} &= \mathbb{E}[x(n)] \\
\\
L_{88} &= 1 \\
L_{89} = L_{98} &= 1 \\
\\
L_{99} &= 1
\end{aligned}$$

The different element of the  $N \times N$  matrix  $M$  are

$$\begin{aligned}
M_{12} = M_{21} &= \mathbb{E}[(a_3 * x^2(n)) \cdot ((a_3 * x(n) + a_2) \cdot x(n))] \\
M_{13} = M_{31} &= \mathbb{E}[(a_3 * x^2(n)) \cdot ((a_3 * x(n) + a_2) \cdot x(n) + a_1)] \\
M_{23} = M_{32} &= \mathbb{E}[((a_3 * x(n) + a_2) \cdot x(n)) \cdot ((a_3 * x(n) + a_2) \cdot x(n) + a_1)] \\
others &= 0
\end{aligned} \tag{24}$$

To decrease the computation time, the symmetry of  $L$  and  $M$  is used. Moreover, the  $M_{ij}$  terms are not computed if there is no correlation between  $b_i$  and  $b_j$ . When there is a correlation between  $b_i$  and  $b_j$ , each noise source  $b_i$  or  $b_j$  is a single quantization noise. In our case, for the matrix  $M$ , only the terms  $M_{12}$ ,  $M_{13}$  and  $M_{23}$  have to be computed ( $M_{21}$ ,  $M_{31}$  and  $M_{32}$  are deduced by symmetry).

## 4 Noise power expression

The global noise power expression is

$$P_{b_y} = \sum_{i=1}^N K_i \cdot \sigma_i^2 + \sum_{i=1}^N \sum_{j=1}^N L_{ij} \cdot \mu_i \cdot \mu_j + \sum_{i=1}^N \sum_{j=1, j \neq i}^N M_{ij} \cdot cov(B_i, B_j) \tag{25}$$

The variable of this expression are  $\sigma_i^2$ ,  $\mu_i$  and  $cov(B_i, B_j)$  which depends on the data word-length and the quantization modes. The  $cov(B_i, B_j)$  term are compute with the table 4.

Let  $q_0$  is the quantization step of the initial data ( $x$  in this example). Let  $q_1$  and  $q_2$  are the quantization step of data quantized and  $k_1$  and  $k_2$  the number of eliminated bits. If the initial data  $x$  is in infinite precision  $q_0$  is equal to zero and  $k_1$  and  $k_2$  tend to infinity.

$Q_1$	$Q_2$	Condition	$cov(B_1, B_2)$
T	T	$k_1 \geq k_2$	$\frac{q_2^2}{12} - \frac{q_0^2}{12}$
T	R	$k_1 \geq k_2$	$-\frac{q_2^2}{24} - \frac{q_0^2}{12}$
R	T	$k_1 > k_2$	$\frac{q_2^2}{12} - \frac{q_0^2}{12}$
R	R	$k_1 = k_2$	$\frac{q_2^2}{12} - \frac{q_0^2}{12}$
R	R	$k_1 > k_2$	$-\frac{q_2^2}{24} - \frac{q_0^2}{12}$

Table 4: Covariance expressions for the different quantization modes of truncation (T) or rounding (R), and for different conditions on  $k_1$  and  $k_2$

## 5 Conclusion

In the context of numerical accuracy evaluation of fixed-point systems, the expressions of the correlation and the covariance between QNSs resulting from the quantization of one unique data has been proposed in this report. The expression of the global output quantization noise integrates correlation between QNSs, which improves the quality of the estimation of the output quantization noise compared to existing approaches. The noise power in the case of a third-order polynomial computation has been described in this report.
