Abstract

We study the problem of receding horizon control for stochastic discrete-time systems with bounded control inputs and incomplete state information. Given a suitable choice of causal control policies, we first present a slight extension of the Kalman filter to estimate the state optimally in mean-square sense. We then show how to augment the underlying optimization problem with a negative drift-like constraint, yielding a second-order cone program to be solved periodically online. We prove that the receding horizon implementation of the resulting control policies renders the state of the overall system mean-square bounded under mild assumptions. We also discuss how some quantities required by the finite-horizon optimization problem can be computed off-line, thus reducing the on-line computation.

Key words: Predictive control, output feedback, constrained control, state estimation, stochastic control

1 Introduction

A considerable amount of research has been devoted to deterministic receding horizon control, see, for example, [35,32] and references therein. This resulted in proofs of recursive feasibility and stability of receding horizon control laws in the noise-free deterministic setting. These techniques can be extended to the robust case, i.e., whenever there is exogenous noise or parametric uncertainty of bounded nature entering the system. The counterpart for stochastic systems subject to process noise, imperfect state measurements, and bounded control inputs, however, is still lacking. The principal obstacle is posed by the fact that it may not be possible to determine an a priori bound on the support of the noise, for example, whenever the noise is additive and Gaussian. This extra ingredient complicates both the stability and the feasibility proofs: the noise, at least in the additive case, eventually drives the state outside any bounded set no

matter how large the latter is taken to be, and employing any standard linear state feedback means that any hard bounds on the control inputs will eventually be violated.

In this article we propose a solution to the general receding horizon control problem for linear systems with noisy process dynamics, imperfect state information, and bounded control inputs. Both the process and measurement noise sequences are assumed to enter the system in an additive fashion, and we require that the designed control policies satisfy hard bounds. Periodically at times $t = 0, N_c, 2N_c, \dots$, where N_c is the control horizon, a certain finite-horizon optimal control problem is solved over a prediction (or optimization) horizon $N \geq N_c$. The cost to be minimized is the standard expectation of the sum of cost-per-stage functions that are quadratic in the state and control inputs [7,8]. We can also include at the design level some variance-like bounds on the predicted future states and inputs—this is one possible way to impose soft state constraints that are in spirit similar to integrated chance-constraints, e.g., in [26,27].

There are several key challenges inherent to our setup. First, since the state information is imperfect one needs a filter to estimate the state. Second, in the presence of unbounded (e.g., Gaussian) noise, it is not possible in general to ensure any bound on the control values gener-

ated via linear state feedback; the additive nature of the noise ensures that the state exits from any fixed bounded set at some time almost surely, implying the necessity of nonlinear feedback policies. This issue is further complicated by the fact that only incomplete state information is available. Third, it is unclear whether the application of the bounded control policies stabilizes the system in any reasonable sense. For a deterministic discrete-time linear system, $x_{t+1} = Ax_t + Bu_t$, it is not possible to globally asymptotically stabilize the system, if the matrix A has unstable eigenvalues, see, for example, [46] and references therein. Moreover, in the presence of stochastic process noise the hope for achieving asymptotic stability is obviously not realistic. In this article we relax the notion of stability to mean-square boundedness of the state and impose the extra conditions that the system matrix A is Lyapunov (or neutrally) stable and that the pair (A, B) is stabilizable.

The main contributions of this paper can be summarized as follows: Given a suitable subclass of bounded causal feedback policies, we show how to augment the finite-horizon optimal control problem to be solved periodically every N_c steps with a *stability constraint* and that the resulting optimization problem can be approximated to a globally feasible second-order cone program (SOCP). Under the assumption that the process and measurement noise are Gaussian, (even though the bounded inputs requirement makes the problem inherently nonlinear and the process statistics are non-Gaussian,) it turns out that Kalman filtering techniques can indeed be utilized. We rely on a low-complexity algorithm (essentially similar to standard Kalman filtering) for updating the conditional density of the state, given the history of the previous outputs, and report tractable solutions for the *off-line* computation of the time-dependent variance and covariance matrices in the optimization program. Finally, we show that the recursive application of the resulting control policies renders the state of the overall system mean-square bounded. This article builds upon and generalizes the earlier stability results in [39,21] that were derived for the perfect state information case. Also, the current results generalize those in [20,16] from the perfect state information case to the imperfect state information case. In particular, if we have full state information available, the control policy proposed in this article reduces to that proposed in [20] and to a special case of the policies proposed in [16] where the vector space is spanned by a single function. However, none of the earlier results, including those in [22], are able to deal with recursive feasibility and stability for the setup of this article. Moreover, the control policy structure in this article is different from that in [22].

Related Work The research on stochastic receding horizon control is broadly subdivided into two parallel lines: the first treats multiplicative noise that enters the state equations, and the second caters to additive

noise. The case of multiplicative noise has been treated in [38,14,18]. In [38], the noise enters the state equation multiplicatively and mixed hard state-input constraints are relaxed into expectation constraints. Terminal constraints are imposed as well that render the overall MPC scheme stable under full state feedback. The authors in [18] treat the case of uncertain output measurement matrix (C) and solve the MPC problem under probabilistic constraints on the outputs and full state feedback. In [14] the stochastic MPC problem is treated under full state feedback and multiplicative noise entering the state equation. The proposed scheme comprises a pre-stabilizing linear state feedback control part and an open-loop part. The pre-stabilizing feedback gain is computed off-line and only the open-loop part is optimized online. The results in [15] extend those in [14] to the case of additive noise as well. However, both results [15] and [14] involve a pre-stabilizing state feedback controller and hence no hard input bounds can be imposed.

We focus in this article on the additive noise case. The approach proposed here stems from and generalizes the idea of affine parametrization of control policies for finite-horizon linear quadratic problems proposed in [3,2], utilized within the robust MPC framework in [2,30,19] for full state feedback, and in [43] for output feedback with Gaussian state and measurement noise inputs. More recently, this affine approximation was utilized in [41] for both the robust deterministic and the stochastic setups in the absence of control bounds, and optimality of affine policies in the scalar deterministic case was reported in [10]. In [9] the authors reformulate the stochastic programming problem as a deterministic one with bounded noise support and solve a robust optimization problem over a finite horizon, followed by estimating the performance when the noise can take unbounded values, i.e., when the noise is unbounded, but takes high values with low probability. A similar approach was utilized in [36] as well. There are also other approaches, e.g., those employing randomized algorithms as in [1,11,33]. Results on obtaining lower bounds on the value functions of the stochastic optimization problem have been recently reported in [44], and a novel stochastic MPC scheme based on the scenario approach has appeared in [5]. Other works employing probabilistic constraints may be found in [40,29]. In [34], an input-to-state stability approach is employed and stability is shown under full state feedback and bounded additive process noise. An MPC scheme for systems with imperfect state information has been proposed in [45] under general hypotheses with probabilistic constraints. However, the ability to deal with noise of an unbounded nature (for example Gaussian) is still absent, in which stability and recursive feasibility could not be proven in [45] under bounded control inputs.

The rest of this article is organized as follows. We formulate the stochastic receding horizon control problem with all the underlying assumptions, the construction of the estimator, and the main optimization problem to

be solved in Section 2. We provide the main results pertaining to tractability of the optimization problem and mean-square boundedness of the closed-loop system in Section 3. We comment on the obtained results and provide some extensions in Section 4. We then present numerical examples in Section 5 and conclude in Section 6. Finally, we provide the proofs in the Appendix.

Notation Let $(\Omega, \mathfrak{F}, \mathbb{P})$ be a general probability space. We denote the conditional expectation given the sub- σ algebra \mathfrak{F}' of \mathfrak{F} as $\mathbb{E}_{\mathfrak{F}'}[\cdot]$. For any random vector s we let $\Sigma_s := \mathbb{E}[ss^\top]$ and $\mathbb{E}_{\mathfrak{Y}_t}[\cdot]$ denote the conditional expectation given \mathfrak{Y}_t . Hereafter we let $\mathbb{N}_+ := \{1, 2, \dots\}$ and $\mathbb{N} := \mathbb{N}_+ \cup \{0\}$. We let $\text{tr}(\cdot)$ denote the trace of a square matrix, $\|\cdot\|_p$ denote the standard p -norm, and simply $\|\cdot\|$ denote the Euclidean norm. We denote by $\|s\|_M := \sqrt{s^\top M s}$ the weighted 2-norm, for $M = M^\top \geq 0$. In a Euclidean space we denote by \mathcal{B}_r the closed Euclidean ball of radius r centered at the origin. For any two matrices A and B of compatible dimensions, we denote by $\mathfrak{R}_k(A, B)$ the k -th step reachability matrix $\mathfrak{R}_k(A, B) := \begin{bmatrix} A^{k-1}B & \dots & AB & B \end{bmatrix}$. For any matrix M , we let σ_{\min} and σ_{\max} be its minimal and maximal singular values, respectively. We let $(M)_{i_1:i_2}$ denote the sub-matrix obtained by selecting the rows i_1 through i_2 of M and $(M)_i$ denote the i -th row of M . For any positive real number s , $\lceil s \rceil$ denotes the smallest integer that upper-bounds s .

2 Problem Setup

Consider the following affine discrete-time stochastic dynamical model:

$$x_{t+1} = Ax_t + Bu_t + w_t, \quad (1a)$$

$$y_t = Cx_t + v_t \quad (1b)$$

where $t \in \mathbb{N}$, $x_t \in \mathbb{R}^n$ is the state, $u_t \in \mathbb{R}^m$ is the control input, $y_t \in \mathbb{R}^p$ is the output, $w_t \in \mathbb{R}^n$ is a random process noise, $v_t \in \mathbb{R}^p$ is a random measurement noise, and A , B , and C are known matrices. We posit the following standing assumption:

Assumption 1

- (i) The pair (A, B) is stabilizable [6, Chapter 12].
- (ii) The matrix A is Lyapunov stable [6, Chapter 12], i.e., the eigenvalues $\{\lambda_i(A) \mid i = 1, \dots, n\}$ lie in the closed unit disc, and those eigenvalues $\lambda_j(A)$ with $|\lambda_j(A)| = 1$ have equal algebraic and geometric multiplicities.
- (iii) The initial condition and the process and measurement noise vectors are mutually independent and normally distributed, i.e., $x_0 \sim \mathcal{N}(0, \Sigma_{x_0})$, $w_t \sim \mathcal{N}(0, \Sigma_w)$, and $v_t \sim \mathcal{N}(0, \Sigma_v)$, with $\Sigma_w > 0$ and $\Sigma_v > 0$.
- (iv) $(A, \Sigma_w^{1/2})$ is controllable and (A, C) is observable.
- (v) The control inputs satisfy

$$\|u_t\|_\infty \leq U_{\max} \quad \forall t \in \mathbb{N}. \quad (2)$$

Without loss of generality, we assume that A is given in real Jordan canonical form. Indeed, given a linear system described by the system matrices (\tilde{A}, \tilde{B}) , there exists a coordinate transformation in the state-space that brings the pair (\tilde{A}, \tilde{B}) to the pair (A, B) , where A is in real Jordan form [23, p. 150]. In particular, choosing a suitable ordering of the Jordan blocks, we can ensure

that the pair (A, B) has the form $\left(\begin{bmatrix} A_s & 0 \\ 0 & A_o \end{bmatrix}, \begin{bmatrix} B_s \\ B_o \end{bmatrix} \right)$,

where $A_s \in \mathbb{R}^{n_s \times n_s}$ is Schur stable, and $A_o \in \mathbb{R}^{n_o \times n_o}$ has its eigenvalues on the unit circle. By Assumption 1-(ii), A_o is therefore block-diagonal with the diagonal blocks being either ± 1 , or 2×2 rotation matrices. As a consequence, A_o is orthogonal. Moreover, since (A, B) is stabilizable, the pair (A_o, B_o) must be reachable in a number of steps $\kappa \leq n_o$ that depends on the dimension of A_o . Therefore, we can start by considering that the state equation (1a) has the form

$$\begin{bmatrix} x_{t+1}^s \\ x_{t+1}^o \end{bmatrix} = \begin{bmatrix} A_s x_t^s \\ A_o x_t^o \end{bmatrix} + \begin{bmatrix} B_s \\ B_o \end{bmatrix} u_t + \begin{bmatrix} w_t^s \\ w_t^o \end{bmatrix}, \quad (3)$$

where A_s is Schur stable, A_o is orthogonal, and there exists a nonnegative integer $\kappa \leq n_o$ such that the subsystem (A_o, B_o) is reachable in κ steps. This reachability index κ is fixed throughout the rest of the article.

For each $t \in \mathbb{N}$, let $\mathfrak{Y}_t := \{y_0, \dots, y_t\}$ denote the set of output observations up to time t . Fix a prediction horizon $N \in \mathbb{N}_+$, with $N \geq \kappa$, and define the cost \mathcal{J}_t as

$$\mathcal{J}_t = \mathbb{E}_{\mathfrak{Y}_t} \left[\sum_{k=0}^{N-1} (\|x_{t+k}\|_{Q_k}^2 + \|u_{t+k}\|_{R_k}^2) + \|x_{t+N}\|_{Q_N}^2 \right], \quad (4)$$

where $Q_k = Q_k^\top \geq 0$, $Q_N = Q_N^\top \geq 0$, and $R_k = R_k^\top \geq 0$ are given matrices of appropriate dimension, for $k = 0, \dots, N-1$.

The evolution of the system (1a)-(1b) over a single prediction horizon N , starting at t , can be described in a compact form as

$$X_t = Ax_t + \mathcal{B}U_t + \mathcal{D}W_t, \quad Y_t = CX_t + V_t, \quad (5)$$

where $X_t = \begin{bmatrix} x_t \\ x_{t+1} \\ \vdots \\ x_{t+N} \end{bmatrix}$, $U_t = \begin{bmatrix} u_t \\ u_{t+1} \\ \vdots \\ u_{t+N-1} \end{bmatrix}$, $W_t = \begin{bmatrix} w_t \\ w_{t+1} \\ \vdots \\ w_{t+N-1} \end{bmatrix}$, $Y_t = \begin{bmatrix} y_t \\ y_{t+1} \\ \vdots \\ y_{t+N} \end{bmatrix}$, $V_t = \begin{bmatrix} v_t \\ v_{t+1} \\ \vdots \\ v_{t+N} \end{bmatrix}$, $\mathcal{A} = \begin{bmatrix} I \\ A \\ \vdots \\ A^N \end{bmatrix}$, $\mathcal{B} = \begin{bmatrix} 0 & \dots & \dots & 0 \\ B & \ddots & \vdots & \vdots \\ AB & B & \ddots & \vdots \\ \vdots & \vdots & \ddots & 0 \\ A^{N-1}B & \dots & AB & B \end{bmatrix}$, $\mathcal{D} = \begin{bmatrix} 0 & \dots & \dots & 0 \\ I & \ddots & \vdots & \vdots \\ A & I & \ddots & \vdots \\ \vdots & \vdots & \ddots & 0 \\ A^{N-1} & \dots & A & I \end{bmatrix}$, and

$C = \text{diag}\{C, \dots, C\}$. The cost function (4) at time t can also be written compactly as

$$\mathcal{J}_t = \mathbb{E}_{\mathcal{Y}_t} [\|X_t\|_{\mathcal{Q}}^2 + \|U_t\|_{\mathcal{R}}^2], \quad (6)$$

where $\mathcal{Q} = \text{diag}\{Q_0, \dots, Q_N\}$ and $\mathcal{R} = \text{diag}\{R_0, \dots, R_{N-1}\}$. The cost \mathcal{J}_t in (4) is a conditional expectation given the observations up to time t , the evaluation of which requires the conditional density $f(x_t|\mathcal{Y}_t)$ of the state given the previous and current measurements. For $t, s \in \mathbb{N}$, define $\hat{x}_{t|s} = \mathbb{E}_{\mathcal{Y}_s}[x_t]$ and $P_{t|s} = \mathbb{E}_{\mathcal{Y}_s}[(x_t - \hat{x}_{t|s})(x_t - \hat{x}_{t|s})^\top]$.

The following result is a slight extension of the standard Kalman filter. A proof may be found in [28, p.102].

Proposition 2 *Let Assumption 1-(iii) hold and assume that u_t is a deterministic function of \mathcal{Y}_t . Then $f(x_t|\mathcal{Y}_t)$ and $f(x_{t+1}|\mathcal{Y}_t)$ are the probability densities of Gaussian distributions $\mathcal{N}(\hat{x}_{t|t}, P_{t|t})$ and $\mathcal{N}(\hat{x}_{t+1|t}, P_{t+1|t})$, respectively, with $P_{t|t} \geq 0$ and $P_{t+1|t} \geq 0$. For $t = -1, 0, 1, 2, \dots$, their conditional means and covariances can be computed iteratively starting at $(\hat{x}_{0|-1}, P_{0|-1}) := (0, \Sigma_{x_0})$, as follows:*

$$\begin{aligned} \hat{x}_{t+1|t+1} &= \hat{x}_{t+1|t} \\ &+ P_{t+1|t} C^\top (C P_{t+1|t} C^\top + \Sigma_v)^{-1} (y_{t+1} - C \hat{x}_{t+1|t}) \end{aligned} \quad (7)$$

$$\begin{aligned} P_{t+1|t+1} &= P_{t+1|t} \\ &- P_{t+1|t} C^\top (C P_{t+1|t} C^\top + \Sigma_v)^{-1} C P_{t+1|t} \end{aligned} \quad (8)$$

$$\hat{x}_{t+1|t} = A \hat{x}_{t|t} + B u_t \quad (9)$$

$$P_{t+1|t} = A P_{t|t} A^\top + \Sigma_w. \quad (10)$$

Proposition 2 states that the conditional mean and covariances of x_t can be propagated by an iterative algorithm which resembles the Kalman filter. In particular, the matrix $P_{t|t}$ together with $\hat{x}_{t|t}$ characterize the conditional density $f(x_t|\mathcal{Y}_t)$, which is needed in the computation of the cost (4) (or equivalently (6)). We note here that in the receding horizon control case considered in this paper u_t will be a nonlinear function of $\{y_0, \dots, y_t\}$; therefore we cannot assume that all the probability distributions in the problem are Gaussian as in the case of LQG; in fact, the a priori distributions of x_t and of \mathcal{Y}_t are not. Hereafter, we shall denote for notational convenience by \hat{x}_t the estimate $\hat{x}_{t|t}$, and let

$$\hat{x}_t = \left[(\hat{x}_t^s)^\top \ (\hat{x}_t^o)^\top \right]^\top, \quad (11)$$

which corresponds to the Jordan decomposition in (3). Let $K_t := (A P_{t|t} A^\top + \Sigma_w) C^\top (C (A P_{t|t} A^\top + \Sigma_w) C^\top + \Sigma_v)^{-1}$ and define $\Gamma_t := I - K_t C$ and $\Phi_t := \Gamma_t A$. Then, we can write the estimation error vector over a single prediction horizon N as

$$E_t := X_t - \hat{X}_t = \mathcal{F}_t e_t + \mathcal{G}_t W_t - \mathcal{H}_t V_t, \quad (12)$$

$$\text{where } e_t = x_t - \hat{x}_t, \quad \hat{X}_t = \begin{bmatrix} \hat{x}_t \\ \vdots \\ \hat{x}_{t+N} \end{bmatrix}, \quad \mathcal{F}_t = \begin{bmatrix} I \\ \Phi_{t+1} \Phi_t \\ \vdots \\ \Phi_{t+N-1} \dots \Phi_t \end{bmatrix},$$

$$\mathcal{G}_t = \begin{bmatrix} 0 & \dots & 0 & 0 \\ \Gamma_t & \dots & 0 & 0 \\ \Phi_{t+1} \Gamma_t & \dots & 0 & 0 \\ \vdots & & & \vdots \\ \Phi_{t+N-2} \dots \Phi_{t+1} \Gamma_t & \dots & \Gamma_{t+N-2} & 0 \\ \Phi_{t+N-1} \dots \Phi_{t+1} \Gamma_t & \dots & \Phi_{t+N-1} \Gamma_{t+N-2} & \Gamma_{t+N-1} \end{bmatrix},$$

$$\mathcal{H}_t = \begin{bmatrix} 0 & 0 & \dots & 0 & 0 \\ 0 & K_t & \dots & 0 & 0 \\ 0 & \Phi_{t+1} K_t & \dots & 0 & 0 \\ \vdots & \vdots & & \vdots & \vdots \\ 0 & \Phi_{t+N-2} \dots \Phi_{t+1} K_t & \dots & K_{t+N-2} & 0 \\ 0 & \Phi_{t+N-1} \dots \Phi_{t+1} K_t & \dots & \Phi_{t+N-1} K_{t+N-2} & K_{t+N-1} \end{bmatrix}.$$

The innovations sequence can be written as

$$Y_t - \hat{Y}_t = C \mathcal{F}_t e_t + C \mathcal{G}_t W_t + (I - C \mathcal{H}_t) V_t, \quad (13)$$

where $\hat{Y}_t := C \hat{X}_t$. Consequently, the innovations sequence over the prediction horizon is independent of the input vector U_t . Also, under the forgoing assumptions, the error vector e_t is a Gaussian random variable with mean zero and variance $P_{t|t}$.

2.1 Optimization Problem and Control Policies

We would like to minimize the cost (4) over the class of all causal feedback policies. However, this optimization problem is extremely difficult to solve in general [7,8]. Therefore, we restrict attention to a subclass of causal feedback policies for which the optimization problem is tractable. Guided by our earlier approach in [20,16,22,21] and given a control horizon $N_c \geq 1$ and a prediction horizon $N \geq N_c$, we would like to periodically minimize the cost (4) at times $t = 0, N_c, 2N_c, \dots$ over the following class of control policies

$$u_{t+\ell} = \eta_{t+\ell} + \sum_{i=0}^{\ell} \theta_{t+\ell, t+i} \varphi_i(y_{t+i} - \hat{y}_{t+i}), \quad (14)$$

where $\ell = 0, 1, \dots, N-1$, $\hat{y}_i = C \hat{x}_i$ is the output of the estimator, and for any vector $z = (z_1, \dots, z_p) \in \mathbb{R}^p$, $\varphi_i(z) = (\varphi_{i,1}(z_1), \dots, \varphi_{i,p}(z_p))$, where $\varphi_{i,j} : \mathbb{R} \rightarrow \mathbb{R}$ is any function with $\sup_{s \in \mathbb{R}} |\varphi_{i,j}(s)| \leq \varphi_{\max} < \infty$ for some

$\varphi_{\max} > 0$. The feedback gains $\theta_{\ell,i} \in \mathbb{R}^{m \times p}$ and the affine terms $\eta_\ell \in \mathbb{R}^m$ are the decision variables. The value of $u_{t+\ell}$ in (14) depends on the values of the measured outputs from the beginning of the prediction horizon at time t up to time $t + \ell$ only, which requires *finite memory*. Note that we have chosen to saturate the measurements we obtain from the vectors $(y_i - \hat{y}_i)$ before employing

them in the control policy. This allows us to consider unbounded noise and yet ensure bounded policies; neither the process noise nor the measurement noise distributions are defined over a compact domain, in contrast to robust deterministic receding horizon control [35] or other stochastic receding horizon control approaches as in [13]. Moreover, the choice of element-wise saturation functions $\varphi_i(\cdot)$ is left open. As such, we can accommodate standard saturation, piecewise linear, and sigmoidal functions, to name a few. The control policy (14) at time t can be compactly written as

$$U_t = \boldsymbol{\eta}_t + \Theta_t \varphi(Y_t - \hat{Y}_t), \quad (15)$$

where Θ_t has the following (causal) lower block triangular structure

$$\Theta_t := \begin{bmatrix} \theta_{t,t} & 0 & \dots & 0 \\ \theta_{t+1,t} & \theta_{t+1,t+1} & & \vdots \\ \vdots & \vdots & \ddots & 0 \\ \theta_{t+N-1,t} & \theta_{t+N-1,t+1} & \dots & \theta_{t+N-1,t+N-1} \end{bmatrix}, \quad (16)$$

$$\boldsymbol{\eta}_t := \begin{bmatrix} \eta_t \\ \eta_{t+1} \\ \vdots \\ \eta_{t+N-1} \end{bmatrix}, \text{ and } \varphi(Y_t - \hat{Y}_t) := \begin{bmatrix} \varphi_0(y_t - \hat{y}_t) \\ \vdots \\ \varphi_{N-1}(y_{t+N-1} - \hat{y}_{t+N-1}) \end{bmatrix}.$$

Since the innovations vector $Y_t - \hat{Y}_t$ in (13) is not a function of $\boldsymbol{\eta}_t$ and Θ_t , the control inputs U_t in (14) remain affine in the decision variables. This fact is important to show convexity of the optimization problem, as will be seen in the next section. Finally, the constraint (2) can be rewritten as:

$$\|U_t\|_\infty \leq U_{\max} \quad \forall t = 0, N_c, 2N_c, \dots \quad (17)$$

Summarizing, the optimization problem to be solved periodically at times $t = 0, N_c, 2N_c, \dots$ is given by

$$\min_{(\boldsymbol{\eta}_t, \Theta_t)} \left\{ \mathcal{J}_t \mid (5), (15), (16), (17) \right\} \quad (18)$$

3 Main Results

Even if problem (18) is successively feasible every N_c steps, in general the resulting control actions do not guarantee stability of the resulting receding horizon controller. Unlike standard deterministic stability arguments utilized in MPC, see, for example, [35], we *cannot* assume the existence of a compact robust positively invariant terminal region, since the process noise sequence does not have a compact support. Instead, we introduce an additional *stability constraint* which, if recursively feasible, renders the state of the closed-loop system mean-square bounded. Guided by the argument in [39], we then show that this constraint is indeed recursively feasible.

For $t = 0, N_c, 2N_c, \dots$, the state estimate at time $t + N_c$

can be written as

$$\hat{x}_{t+N_c} = A^{N_c} \hat{x}_t + \mathfrak{R}_{N_c}(A, B) \begin{bmatrix} u_t \\ \vdots \\ u_{t+N_c-1} \end{bmatrix} + \Xi_t, \quad (19)$$

where $\mathfrak{R}_{N_c}(A, B)$ is the reachability matrix as defined earlier and Ξ_t is defined as

$$\begin{aligned} \Xi_t := & [A^{N_c-1}K_tCA \ A^{N_c-2}K_{t+1}CA \ \dots \ K_{t+N_c-1}CA] \begin{bmatrix} e_t \\ \vdots \\ e_{t+N_c-1} \end{bmatrix} \\ & + [A^{N_c-1}K_tC \ A^{N_c-2}K_{t+1}C \ \dots \ K_{t+N_c-1}C] \begin{bmatrix} w_t \\ \vdots \\ w_{t+N_c-1} \end{bmatrix} \\ & + [A^{N_c-1}K_t \ A^{N_c-2}K_{t+1} \ \dots \ K_{t+N_c-1}] \begin{bmatrix} v_{t+1} \\ \vdots \\ v_{t+N_c} \end{bmatrix}. \end{aligned} \quad (20)$$

In order to show boundedness of the state variance, we require that the N_c -step iteration (19) has bounded variance. However, this estimate has the term Ξ_t , which involves the error in the state estimation process as well as the process and measurement noise vectors. This term Ξ_t may be viewed as ‘noise’ entering the system, with bounded fourth moment. In particular, we require that there exists, at least after some time T' , a uniform bound on its first moment. This is captured by the following Proposition.

Proposition 3 *There exists an integer T' and a positive constant ζ , depending on the given problem parameters, such that*

$$\mathbb{E}_{\mathcal{Y}_t} [\|\Xi_t\|] \leq \zeta \quad \text{for all } t \geq T'. \quad (21)$$

Using the constant ζ , we now require the following ‘drift condition’ to be satisfied: for any chosen constant $\varepsilon > 0$ and for every $t = 0, N_c, 2N_c, \dots$, $U_t \in \mathbb{U}$ is designed such that the following condition is satisfied

$$\begin{aligned} \left\| A_o^{N_c} \hat{x}_t^o + \mathfrak{R}_{N_c}(A_o, B_o) \begin{bmatrix} u_t \\ \vdots \\ u_{t+N_c-1} \end{bmatrix} \right\| & \leq \|\hat{x}_t^o\| - (\zeta + \frac{\varepsilon}{2}) \\ \text{whenever } \|\hat{x}_t^o\| & \geq \zeta + \varepsilon. \end{aligned} \quad (22)$$

As will be shown later, condition (22) above guarantees that on average the state norm *contracts* every N_c steps, a crucial ingredient towards showing mean-square boundedness of the closed-loop system. Moreover, N_c needs to be chosen appropriately (depending on the reachability index κ) in order to ensure that the constraint is feasible. Note that

$\begin{bmatrix} u_t \\ \vdots \\ u_{t+N_c-1} \end{bmatrix} = (\boldsymbol{\eta}_t)_{1:N_c m} + (\Theta_t)_{1:N_c m} \varphi(Y - \hat{Y})$. (For notational convenience, we have retained $\varphi(Y - \hat{Y})$ with the knowledge that the matrix $(\Theta_t)_{1:N_c m}$ causally selects the first N_c output vectors as they become available, see (16).) We augment

problem (18) with the stability constraint (22) to obtain

$$\min_{(\boldsymbol{\eta}_t, \boldsymbol{\Theta}_t)} \left\{ \mathcal{J}_t \mid (5), (15), (16), (17), (22) \right\}. \quad (23)$$

The ingredients of our stochastic receding horizon control problem corresponding to (23) are summarized in Algorithm 1.

Algorithm 1 Basic Stochastic Receding Horizon Algorithm

Require: density $f(x_0 | \mathcal{Y}_{-1}) := \mathcal{N}(0, \Sigma_{x_0})$

- 1: set $t \leftarrow 0$, $\hat{x}_{0|-1} \leftarrow 0$, and $P_{0|-1} \leftarrow \Sigma_{x_0}$
- 2: **loop**
- 3: **for** $i = 0$ to $N_c - 1$ **do**
- 4: measure y_{t+i}
- 5: calculate $\hat{x}_{t+i} (= \hat{x}_{t+i|t+i})$ and $P_{t+i|t+i}$ using (7)-(8)
- 6: **if** $i = 0$ **then**
- 7: solve the optimization problem (23) for the optimal policy $\{u_t^*, \dots, u_{t+N-1}^*\}$
- 8: **end if**
- 9: using the obtained control policy above, compute and apply u_{t+i}^*
- 10: calculate $\hat{x}_{t+i+1|t+i}$ and $P_{t+i+1|t+i}$ using (9)-(10)
- 11: **end for**
- 12: set $t \leftarrow t + N_c$
- 13: **end loop**

Assumption 4 We require that:

- (i) The control and prediction horizons satisfy $N \geq N_c = \kappa$, where κ is the reachability index of the orthogonal subsystem (A_o, B_o) in (3).
- (ii) The control authority $U_{\max} \geq U_{\max}^*$, where $U_{\max}^* := \sigma_{\min}(\mathfrak{R}_{N_c}(A_o, B_o))^{-1}(\zeta + \frac{\varepsilon}{2})$ and $\mathfrak{R}_{N_c}(A_o, B_o)$ is the N_c -step reachability matrix of the orthogonal subsystem.

In fact, choosing any control horizon $N_c \geq \kappa$ turns out to be sufficient in order to have a feasible control vector U_t for problem (23) with an upper bound $U_{\max} = U_{\max}^*$; however, we will take $N_c = \kappa$ for simplicity.

Theorem 5 Consider the system (1a)-(1b), and suppose that Assumptions 1 and 4 hold. Then:

- (i) For every time $t = 0, N_c, 2N_c, \dots$, the optimization problem (23) in Algorithm 1 is convex and can be conservatively approximated and solved via the following globally (hence recursively) feasible second-order cone program (SOCP):

$$\begin{aligned} & \underset{(z_1, z_2, z_3, \boldsymbol{\eta}_t, \boldsymbol{\Theta}_t)}{\text{minimize}} && z_1 \\ & \text{subject to} && \\ & \|\boldsymbol{\eta}_t + \boldsymbol{\Theta}_t \Lambda_t^\varphi\|_{\mathcal{M}}^2 + \text{tr}\left(\boldsymbol{\Theta}_t^\top \mathcal{M} \boldsymbol{\Theta}_t (\Lambda_t^{\varphi\varphi} - \Lambda_t^\varphi \Lambda_t^{\varphi\top})\right) + \\ & 2\hat{x}_t^\top \mathcal{A}^\top \mathcal{Q} \mathcal{B} \boldsymbol{\eta}_t + 2\text{tr}\left(\boldsymbol{\Theta}_t^\top \mathcal{B}^\top \mathcal{Q} (\mathcal{D} \Lambda_t^{w\varphi} + \mathcal{A} \Lambda_t^{x\varphi})\right) \leq z_1 \end{aligned} \quad (24)$$

$$\|(\boldsymbol{\eta}_t)_i\| + \|(\boldsymbol{\Theta}_t)_i\|_1 \varphi_{\max} \leq U_{\max} \quad \forall i = 1, \dots, Nm, \quad (26)$$

$$\left. \begin{aligned} & \|A_o^{N_c} \hat{x}_t^o + \mathfrak{R}_{N_c}(A_o, B_o)(\boldsymbol{\eta}_t)_{1:N_c m}\| \leq z_2 \\ & \|\mathfrak{R}_{N_c}(A_o, B_o)(\boldsymbol{\Theta}_t)_{1:N_c m}\|_\infty \leq z_3 \\ & z_2 + \sqrt{n_o} \varphi_{\max} z_3 \leq \|\hat{x}_t^o\| - (\zeta + \frac{\varepsilon}{2}) \end{aligned} \right\} \text{whenever } \|\hat{x}_t^o\| \geq \zeta + \varepsilon \quad (27)$$

the structure of $\boldsymbol{\Theta}_t$ in (16),

where $\mathcal{M} := \mathcal{R} + \mathcal{B}^\top \mathcal{Q} \mathcal{B}$, and

$$\begin{aligned} \Lambda_t^\varphi &:= \mathbb{E}_{\mathcal{Y}_t}[\varphi(Y_t - \hat{Y}_t)], \quad \Lambda_t^{x\varphi} := \mathbb{E}_{\mathcal{Y}_t}[x_t \varphi(Y_t - \hat{Y}_t)^\top], \\ \Lambda_t^{w\varphi} &:= \mathbb{E}_{\mathcal{Y}_t}[W \varphi(Y_t - \hat{Y}_t)^\top], \\ \Lambda_t^{\varphi\varphi} &:= \mathbb{E}_{\mathcal{Y}_t}[\varphi(Y_t - \hat{Y}_t) \varphi(Y_t - \hat{Y}_t)^\top]. \end{aligned} \quad (28)$$

- (ii) The application of Algorithm 1 via the SOCP approximation in part (i) above renders the closed-loop system mean-square bounded, i.e., for any initial \mathcal{Y}_0 , there exists a (computable) finite constant $\gamma > 0$, depending on the given problem parameters, such that

$$\sup_{t \in \mathbb{N}} \mathbb{E}_{\mathcal{Y}_0}[\|x_t\|^2] \leq \gamma. \quad (29)$$

In practice, it may be also of interest to further impose constraints both on the state and the input vectors. For example, one may be interested in imposing linear and / or quadratic constraints on the state of the form

$$\mathbb{E}_{\mathcal{Y}_t} \left[\|X_t\|_{\mathcal{S}}^2 + \mathcal{L}^\top X_t \right] \leq \alpha_t, \quad (30)$$

where $\mathcal{S} = \mathcal{S}^\top \geq 0$ and $\alpha_t > 0$. Moreover, expected energy expenditure constraints can be posed as follows

$$\mathbb{E}_{\mathcal{Y}_t} \left[\|U_t\|_{\tilde{\mathcal{S}}}^2 \right] \leq \beta_t, \quad (31)$$

where $\tilde{\mathcal{S}} = \tilde{\mathcal{S}}^\top \geq 0$ and $\beta_t > 0$. In the absence of hard input constraints, such expectation-type constraints are commonly used in the stochastic MPC [38,17] and in stochastic optimization in the form of integrated chance constraints [26,27]. This is partly because it is not possible, without posing further restrictions on the boundedness of the process noise w_t , to ensure that hard constraints on the state are satisfied. For example, in the standard LQG setting nontrivial hard constraints on the system state would generally be violated with nonzero probability. Moreover, in contrast to chance constraints where a bound is imposed on the probability of constraint violation, expectation-type constraints tend to give rise to convex optimization problems under weak assumptions [17,26,27]. We can augment problem (23) with the constraints (30) and (31) to obtain

$$\min_{(\boldsymbol{\eta}_t, \boldsymbol{\Theta}_t)} \left\{ \mathcal{J}_t \mid (5), (15), (16), (17), (22), (30), (31) \right\}. \quad (32)$$

Notice that the constraints (30) and (31) are not necessarily feasible at time t for any choice of parameters α_t and β_t . As such, problem (32) may become infeasible over time if we simply apply Algorithm 1. We therefore modify step 7 in Algorithm 1 to generate Algorithm 2. In this new version of the algorithm, problem (32) is either feasible at step 7 with the given α_t and β_t , or a bisection search is implemented (steps 12 to 26), with α_t and β_t as lower bounds, and upper bounds

$$\begin{aligned}\alpha_t^* &:= 3\text{tr}(\mathcal{A}^\top \mathcal{S} \mathcal{A} \mathbb{E}_{\mathcal{Y}_t} [x_t x_t^\top] + \mathcal{D}^\top \mathcal{S} \mathcal{D} \Sigma_w) + \mathcal{L}^\top \mathcal{A} \hat{x}_t \\ &\quad + 3Nm\sigma_{\max}(\mathcal{B}^\top \mathcal{S} \mathcal{B}) U_{\max}^2 + \|\mathcal{L}^\top \mathcal{B}\|_1 U_{\max} \\ \beta_t^* &:= Nm\sigma_{\max}(\tilde{\mathcal{S}}) U_{\max}^2\end{aligned}\quad (33)$$

that guarantee feasibility. The search is iterated until the change in α and β falls below a prespecified precision number δ or a maximal number of iterations $\bar{\nu}$ is reached, which is used to keep the computational burden limited.

Corollary 6 Consider the system (1a)-(1b), and suppose that Assumptions 1 and 4 hold. Then:

- (i) For every time $t = 0, N_c, 2N_c, \dots$ the optimization problem (32) in Algorithm 2 is convex and can be conservatively approximated and solved via the following globally (hence recursively) feasible (at either step 7 or step 13) second-order cone program (SOCP):

$$\begin{aligned}& \underset{(z_1, z_2, z_3, \boldsymbol{\eta}_t, \Theta_t)}{\text{minimize}} \quad z_1 \\ & \text{subject to} \\ & \|\boldsymbol{\eta}_t + \Theta_t \Lambda_t^\varphi\|_{\mathcal{M}}^2 + \text{tr}\left(\Theta_t^\top \mathcal{M} \Theta_t (\Lambda_t^{\varphi\varphi} - \Lambda_t^\varphi \Lambda_t^{\varphi\top})\right) + \\ & 2\hat{x}_t^\top \mathcal{A}^\top \mathcal{Q} \mathcal{B} \boldsymbol{\eta}_t + 2\text{tr}\left(\Theta_t^\top \mathcal{B}^\top \mathcal{Q} (\mathcal{D} \Lambda_t^{w\varphi} + \mathcal{A} \Lambda_t^{x\varphi})\right) \leq z_1 \\ & |(\boldsymbol{\eta}_t)_i| + \|(\Theta_t)_i\|_1 \varphi_{\max} \leq U_{\max} \quad \forall i = 1, \dots, Nm, \\ & \left. \begin{aligned} & \|A_o^{N_c} \hat{x}_t^o + \mathfrak{R}_{N_c}(A_o, B_o)(\boldsymbol{\eta}_t)_{1:N_c m}\| \leq z_2 \\ & \|\mathfrak{R}_{N_c}(A_o, B_o)(\Theta_t)_{1:N_c m}\|_\infty \leq z_3 \\ & z_2 + \sqrt{n_o} \varphi_{\max} z_3 \leq \|\hat{x}_t^o\| - (\zeta + \frac{\varepsilon}{2}) \end{aligned} \right\} \text{whenever} \\ & \|\boldsymbol{\eta}_t + \Theta_t \Lambda_t^\varphi\|_{\mathcal{B}^\top \mathcal{S} \mathcal{B}}^2 + \text{tr}\left(\Theta_t^\top \mathcal{B}^\top \mathcal{S} \mathcal{B} \Theta_t (\Lambda_t^{\varphi\varphi} - \Lambda_t^\varphi \Lambda_t^{\varphi\top})\right) \\ & \quad + 2\hat{x}_t^\top \mathcal{A}^\top \mathcal{S} \mathcal{B} \boldsymbol{\eta}_t + 2\text{tr}\left(\Theta_t^\top \mathcal{B}^\top \mathcal{S} (\mathcal{D} \Lambda_t^{w\varphi} + \mathcal{A} \Lambda_t^{x\varphi})\right) \\ & \quad + \mathcal{L}^\top \mathcal{B} (\boldsymbol{\eta}_t + \Theta_t \Lambda_t^\varphi) + \text{tr}(\mathcal{A}^\top \mathcal{S} \mathcal{A} \mathbb{E}_{\mathcal{Y}_t} [x_t x_t^\top]) \\ & \quad + \text{tr}(\mathcal{D}^\top \mathcal{S} \mathcal{D} \Sigma_w) + \mathcal{L}^\top \mathcal{A} \hat{x}_t \leq \alpha_t \quad (34) \\ & \|\boldsymbol{\eta}_t + \Theta_t \Lambda_t^\varphi\|_{\tilde{\mathcal{S}}}^2 + \text{tr}\left(\Theta_t^\top \tilde{\mathcal{S}} \Theta_t (\Lambda_t^{\varphi\varphi} - \Lambda_t^\varphi \Lambda_t^{\varphi\top})\right) \leq \beta_t \\ & \quad (35)\end{aligned}$$

the structure of Θ_t in (16),

where all the required constant matrices are defined as in Theorem 5.

- (ii) The application of Algorithm 2 via the SOCP approximation in part (i) above renders the closed-loop system mean-square bounded, i.e., for any initial \mathcal{Y}_0 , there exists a (computable) finite constant $\gamma > 0$, de-

pending on the given problem parameters, such that

$$\sup_{t \in \mathbb{N}} \mathbb{E}_{\mathcal{Y}_0} [\|x_t\|^2] \leq \gamma. \quad (36)$$

Algorithm 2 Modified Stochastic Receding Horizon Algorithm

Require: density $f(x_0 | \mathcal{Y}_{-1}) := \mathcal{N}(0, \Sigma_{x_0})$

- 1: set $t \leftarrow 0$, $\hat{x}_{0|-1} \leftarrow 0$, and $P_{0|-1} \leftarrow \Sigma_{x_0}$
 - 2: **loop**
 - 3: **for** $i = 0$ to $N_c - 1$ **do**
 - 4: measure y_{t+i}
 - 5: calculate $\hat{x}_{t+i} (= \hat{x}_{t+i|t+i})$ and $P_{t+i|t+i}$ using (7)-(8)
 - 6: **if** $i = 0$ **then**
 - 7: solve the optimization problem (32) using the given α_t and β_t
 - 8: **if** step 7 is feasible **then**
 - 9: save the optimal sequence $\{u_t^*, u_{t+1}^*, \dots, u_{t+N-1}^*\}$
 - 10: goto step 28
 - 11: **else**
 - 12: set $\bar{\alpha} \leftarrow \alpha_t^*$, $\underline{\alpha} \leftarrow \alpha_t$, $\bar{\beta} \leftarrow \beta_t^*$, and $\underline{\beta} \leftarrow \beta_t$
 - 13: solve the optimization problem (32) using $\bar{\alpha}$ and $\bar{\beta}$ to obtain the sequence $\{u_t^*, u_{t+1}^*, \dots, u_{t+N-1}^*\}$
 - 14: set $\nu \leftarrow 1$
 - 15: **repeat**
 - 16: set $\alpha_t \leftarrow (\bar{\alpha} + \underline{\alpha})/2$ and $\beta_t \leftarrow (\bar{\beta} + \underline{\beta})/2$
 - 17: solve the optimization problem (32) using the new α_t and β_t
 - 18: **if** step 17 is feasible **then**
 - 19: set $\bar{\alpha} \leftarrow \alpha_t$ and $\bar{\beta} \leftarrow \beta_t$
 - 20: save the new optimal sequence $\{u_t^*, u_{t+1}^*, \dots, u_{t+N-1}^*\}$
 - 21: **else**
 - 22: set $\underline{\alpha} \leftarrow \alpha_t$ and $\underline{\beta} \leftarrow \beta_t$
 - 23: **end if**
 - 24: set $\nu = \nu + 1$
 - 25: **until** $(|\bar{\alpha} - \underline{\alpha}| \leq \delta$ and $|\bar{\beta} - \underline{\beta}| \leq \delta)$ or $(\nu > \bar{\nu})$
 - 26: **end if**
 - 27: **end if**
 - 28: apply u_{t+i}^*
 - 29: calculate $\hat{x}_{t+i+1|t+i}$ and $P_{t+i+1|t+i}$ using (9)-(10)
 - 30: **end for**
 - 31: set $t = t + N_c$
 - 32: **end loop**
-

4 Discussion

4.1 Recursive Feasibility

The SOCPs solved in Theorem 5 and Corollary 6 are globally feasible, independently of the initial conditions of the plant and the estimator. As such, there is no a priori requirement for an initially feasible and invariant

set of initial conditions, as is the case in nominal or robust receding horizon control [35]. This guarantee of recursive feasibility is shown in the proofs of Theorem 5 and Corollary 6 by providing a feasible control law that satisfies all the constraints in the SOCPs.

4.2 Mean-Square Boundedness

The mean-square boundedness conditions (29) and (36) provide an on-average guarantee that the state does not grow arbitrarily large. This is a weaker notion of stability than, for example, asymptotic stability or input-to-state stability (ISS) that have been utilized in nominal and robust receding horizon control, respectively. However, in the presence of possibly unbounded process and measurement noise, it is virtually impossible to guarantee that the state converges to the origin or that it is ultimately bounded in some compact set for every initial condition and every realization of the noise processes. In this case, similarly to LQG (i.e., even with unbounded control authority), mean-square boundedness is the best that can be aimed for within our setting, given the unboundedness of the noise processes and the limited control authority. The constants γ in (29) and (36) may be computed using the derivations in the Appendix and the formulas in the Remark in [37, pp.145].

4.3 More General Policies

It is not difficult to show that one can also use quadratic policies of the form

$$U_t = \boldsymbol{\eta}_t + \boldsymbol{\Theta}_t \varphi(Y_t - \hat{Y}_t) + \tilde{\boldsymbol{\Theta}}_t \tilde{\varphi}(Y_t - \hat{Y}_t), \quad (37)$$

instead of (14), where $\tilde{\boldsymbol{\Theta}}_t$ has the same causal structure of $\boldsymbol{\Theta}_t$ and $\tilde{\varphi}(Y_t - \hat{Y}_t) := [\tilde{\varphi}_0(y_t - \hat{y}_t) \dots \tilde{\varphi}_{N-1}(y_{t+N-1} - \hat{y}_{t+N-1})^\top \tilde{\varphi}_{N-1}(y_{t+N-1} - \hat{y}_{t+N-1})]^\top$, with $\sup_{s \in \mathbb{R}} |\tilde{\varphi}_i(s)| \leq \tilde{\varphi}_{\max} < \infty$ for some $\tilde{\varphi}_{\max} > 0$. The underlying optimization problems (23) and (32) with the policy (37) are still convex and both Theorem 5 and Corollary 6 still apply with minor changes.

4.4 Off-Line Computation of the Λ Matrices

The optimization problems (23) and (32) solved in Theorem 5 and in Corollary (6), respectively, are second-order cone programs (SOCP) for which efficient numerical solvers are available via software packages such as `yalmip` [31]. As such, the optimization may be performed online. However, at any time $t = 0, N_c, 2N_c, \dots$, our ability to solve the optimization problems in Theorem 5 and Corollary 6, respectively, hinges upon the computation of the matrices in (28).

Recall that $Y_t - \hat{Y}_t$ is the innovations sequence that was given in (13), and that \hat{x}_t is the optimal mean-square estimate of x_t given the history \mathcal{Y}_t . The matrices (28) may be computed by numerical integration with respect to the independent Gaussian measures of w_t, \dots, w_{t+N-1} , of v_t, \dots, v_{t+N} , and of $(x_t - \hat{x}_t)$ given \mathcal{Y}_t . Due to the large dimensionality of the integration

space, this approach may be impractical for online computations. One alternative approach relies on the observation that Λ_t^φ , $\Lambda_t^{w\varphi}$, and $\Lambda_t^{\varphi\varphi}$ depend on x_t via the difference $x_t - \hat{x}_t$. Since $x_t - \hat{x}_t$ is conditionally zero-mean given \mathcal{Y}_t , we can write the dependency of (28) on the time-varying statistics of x_t given \mathcal{Y}_t as follows: $\Lambda_t^{x\varphi}(\hat{x}_t, P_{t|t}) = \Lambda_t^{e\varphi}(P_{t|t}) + \hat{x}_t \Lambda_t^\varphi(P_{t|t})^\top$, $\Lambda_t^{w\varphi}(P_{t|t})$, and $\Lambda_t^{\varphi\varphi}(P_{t|t})$, where $\Lambda_t^{e\varphi} := \mathbb{E}_{\mathcal{Y}_t}[(x_t - \hat{x}_t)\varphi(Y_t - \hat{Y}_t)^\top]$. In principle one may compute *off-line* and store the matrices $\Lambda_t^{e\varphi}(P_{t|t})$, $\Lambda_t^\varphi(P_{t|t})$, $\Lambda_t^{w\varphi}(P_{t|t})$, and $\Lambda_t^{\varphi\varphi}(P_{t|t})$, which depend on the covariance matrices $P_{t|t}$ but not on \hat{x}_t , and just update online the value of $\Lambda_t^{x\varphi}(\hat{x}_t, P_{t|t})$ as the estimate \hat{x}_t becomes available. However, this poses serious requirements in terms of memory. A more appealing alternative is to exploit the convergence properties of the covariance matrix $P_{t|t}$. The following result can be inferred, for instance, from [25, Theorem 5.1].

Proposition 7 *Under Assumption 1-(iii) and (iv) the discrete-time algebraic Riccati equation in $P \in \mathbb{R}^{n \times n}$, $P = A[P - PC^\top(CPC^\top + \Sigma_v)^{-1}CP]A^\top + \Sigma_w$, has a unique solution $P^* \geq 0$. The sequence $P_{t+1|t}$ defined by (8) and (10) converges to P^* as t tends to ∞ , for any initial condition $P_{0|-1} \geq 0$.*

As a consequence, from (8) one sees that $P_{t|t}$ converges to $P^\circ = P^* - P^*C^\top(CP^*C^\top + \Sigma_v)^{-1}CP^*$, which is the asymptotic error covariance matrix of the estimator \hat{x}_t . Thus, neglecting the initial transient, one may just compute off-line and store the matrices $\Lambda_t^{e\varphi}(P^\circ)$, $\Lambda_t^\varphi(P^\circ)$, $\Lambda_t^{w\varphi}(P^\circ)$, and $\Lambda_t^{\varphi\varphi}(P^\circ)$, and just update the matrix $\Lambda_t^{x\varphi}(\hat{x}_t, P^\circ)$ for new values of the estimate \hat{x}_t .

5 Simulations

Consider the system (1a)-(1b) with the following matrices:

$$A = \begin{bmatrix} 0.9 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & \cos(\psi) & -\sin(\psi) \\ 0 & 0 & \sin(\psi) & \cos(\psi) \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ 1 \\ 0 \\ 1 \end{bmatrix}, \quad \text{and } C = I,$$

where $\psi = \frac{\pi}{2}$. The orthogonal part of the state is 3-dimensional, and the controllability index of the orthogonal part is $\kappa = 3$.

Example 1. The simulation data was chosen to be: $x_0 \sim \mathcal{N}(0, I)$, $w_t \sim \mathcal{N}(0, 10I)$, $v_t = \mathcal{N}(0, 10I)$, $Q = I$, $R = 1$, $N = 5$, $N_c = \kappa = 3$, and φ the usual piecewise linear saturation function with $\varphi_{\max} = 1$. For this example the theoretical bound on the input is $U_{\max} \doteq 453$ for a choice of $\varepsilon = 10$.

We simulated the system above using Algorithm 1 for the discrete-time interval $[0, 100]$. In comparison, we simulated also the policy (38) proposed by the authors in [39] whenever the state is estimated using a Kalman filter, with the understanding that this goes beyond the results in [39], since [39] deals only with the case of perfect state information. We also simulated the standard LQG controller for this system with post-saturation of the obtained controls. The average state norm as well as the standard deviation of the state norm using the three strategies are depicted in Figure 1 and the total costs are plotted in Figure 2. Figure 2 shows approximately 16%

improvement in the cost after 100 time steps by using Algorithm 1 versus the policy (38) in [39] coupled with a Kalman filter. The performance of our policy is close to that of clipped LQG, which remains mean-square ‘optimal’ since the theoretical upper bound on the control authority is never reached by the LQG policy, i.e., the LQG policy is never clipped (for our choice of initial condition x_0). The optimization problem was solved using `yalmip` [31] and `sdpt3` [42] and the solver times were as follows: minimum = 0.1238 second, maximum = 0.5831 second, average = 0.1691 second, and standard deviation = 0.0144 second. This data pertains to an Intel(R) Core(TM)2 Duo CPU running at 2.66GHz, with a Linux operating system. The computation of the matrices $\Lambda^{e\varphi}(P^\circ)$, $\Lambda^\varphi(P^\circ)$, $\Lambda^{w\varphi}(P^\circ)$, and $\Lambda^{\varphi\varphi}(P^\circ)$ was done off-line using the steady state error covariance matrix P° , as discussed in the previous section, via classical Monte Carlo integration using 10^5 samples.

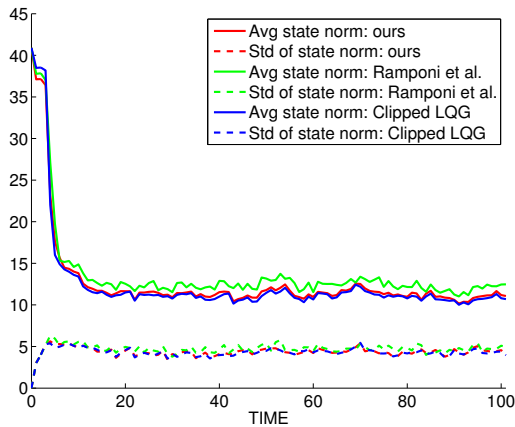

Fig. 1. Average and standard deviation of the state norm for $U_{\max} = 453$

Fig. 2. Total cost for $U_{\max} = 453$

Example 2. We also simulated the same system as before with $Q = 100I$ and $R = 1$. In this case the theoretical bound $\zeta = 336.6$ and the corresponding $U_{\max} = 440.45$.

As this theoretical bound on ζ is conservative, we reduced ζ down to 2 and chose $\varepsilon = 0.5$, which result in $U_{\max} = 3.2664$. This choice of ζ is far below the required theoretical bound (which was given in Example 1 above) and as such the stability guarantees in the article do not apply anymore, i.e., there is no theoretical guarantee that the closed-loop system is mean-square bounded. However, it is apparent from Figures 3 and 4 that our policy is stabilizing. It is important to notice that the clipped LQG policy hits the saturation level U_{\max} quite often, whereas our policy does not, as seen in Figure 5. However, despite the fact that our strategy does not take full advantage of the available control authority, it is still able to outperform the clipped LQG as well as the adapted policy in [39].

6 Conclusions

We presented a method for stochastic receding horizon control of discrete-time linear systems with process and measurement noise and bounded input policies. We showed that the optimization problem solved periodically is successively feasible and convex. Moreover, we illustrated how a certain stability condition can be utilized

Fig. 5. Average inputs for $U_{\max} = 3.2664$

to ensure that the application of the receding horizon controller renders the state of the system mean-square bounded. We discussed how certain matrices in the cost function can be computed off-line and provided examples that illustrate our approach, showing conditions under which it outperforms certain competing approaches.

Appendix: Proofs

We begin by considering the estimation equation in (7) and combining it with (9) and the system dynamics (1a)-(1b) to obtain (recall that \hat{x}_t is used instead of $\hat{x}_{t|t}$ for notational simplicity) $\hat{x}_{t+1} = A\hat{x}_t + Bu_t + K_t(CA(x_t - \hat{x}_t) + Cw_t + v_{t+1})$, where $K_t = (AP_{t|t}A^\top + \Sigma_w)C^\top(C(AP_{t|t}A^\top + \Sigma_w)C^\top + \Sigma_v)^{-1}$ and $P_{t|t}$ is the error covariance matrix defined in (8). Both K_t and P_t are uniformly norm-bounded as shown in the following Lemma:

Lemma 8 *Consider the system (1a)-(1b), and let Assumption 1-(iv) hold. In addition, assume that $P_{0|0} \geq 0$. Then, there exists a time $T' \in \mathbb{N}$ and constants $\rho, \rho_m > 0$ such that $\text{tr}(P_{t|t}) \leq \rho$ and $\|K_t\| \leq \rho_m, \forall t \geq T'$.*

PROOF. First, observe that $\sum_{i=0}^{\kappa_1-1} A^i \Sigma_w (A^i)^\top = \left[\Sigma_w^{1/2} A \Sigma_w^{1/2} \dots A^{\kappa_1-1} \Sigma_w^{1/2} \right] \left[\Sigma_w^{1/2} A \Sigma_w^{1/2} \dots A^{\kappa_1-1} \Sigma_w^{1/2} \right]^\top$,

and since $(A, \Sigma_w^{1/2})$ is controllable by Assumption 4-(iv), we see that there exists $\kappa_1 \in \mathbb{N}_+$ such that for all $k \geq \kappa_1$ the rank of $\left[\Sigma_w^{1/2} A \Sigma_w^{1/2} \dots A^{\kappa_1-1} \Sigma_w^{1/2} \right] = n$;

indeed, κ_1 is the reachability index of $(A, \Sigma_w^{1/2})$. Thus, $\sum_{i=0}^{\kappa_1-1} A^i \Sigma_w (A^i)^\top$ is positive definite, and therefore, there exists some $\delta'_1, \delta'_2 > 0$ such that $\delta'_1 I \leq \sum_{i=0}^{\kappa_1-1} A^i \Sigma_w (A^i)^\top \leq \delta'_2 I$. Second, observe

that $\sum_{i=0}^{\kappa_2-1} (A^i)^\top C^\top \Sigma_v^{-1} C A^i = \begin{bmatrix} C \\ CA \\ \vdots \\ CA^{\kappa_2-1} \end{bmatrix}^\top (I_{\kappa_2} \otimes \Sigma_v^{-1}) \begin{bmatrix} C \\ CA \\ \vdots \\ CA^{\kappa_2-1} \end{bmatrix}$, where \otimes denotes the standard Kronecker product.

Since (A, C) is observable by assumption, there exists $\kappa_2 \in \mathbb{N}_+$ such that the rank of the matrix $\left[C^\top A^\top C^\top \dots (A^{\kappa_2-1})^\top C^\top \right]^\top$ is n . The matrix $I_{\kappa_2} \otimes \Sigma_v^{-1}$ is clearly positive definite by Assumption 4-(iv), and therefore, we see that there exists $\delta''_1, \delta''_2 > 0$ such that $\delta''_1 I \leq \sum_{i=0}^{\kappa_2-1} (A^i)^\top C^\top \Sigma_v^{-1} C A^i \leq \delta''_2 I$. Third, the conditions of Lemma 7.1 in [24, pp. 234] are satisfied, for a choice of $\delta_1 = \min\{\delta'_1, \delta''_1\}$ and $\delta_2 = \max\{\delta'_2, \delta''_2\}$, and the bound $P_{t|t} \leq \rho' I$ for some $\rho' > 0$ is established for all $t \geq T' := \max\{\kappa_1, \kappa_2\}$. The assertion now follows immediately from: $\mathbb{E}_{y_t} [\|x_t - \hat{x}_t\|^2] = \text{tr}(P_{t|t}) \leq n \lambda_{\max}(P_{t|t}) \leq n \rho' =: \rho$. Since by assumption $\Sigma_v > 0$, one possible bound on $(\|K_t\|)_{t \geq T'}$ is given by $\|K_t\| \leq \frac{\|AP_{t|t}A^\top + \Sigma_w\| \|C^\top\|}{\lambda_{\min}(\Sigma_v)} \leq \frac{(\|\Sigma_w\| + \|A\|^2 \|P_{t|t}\|) \|C^\top\|}{\lambda_{\min}(\Sigma_v)} =: \rho_m$. \square

Using the bounds in Lemma 8, we can proceed to prove Proposition 3.

PROOF. [Proof of Proposition 3] Recall the expression of Ξ_t in (20) and define the following quantities:

$$F_t := \begin{bmatrix} A^{N_c-1}K_tCA & A^{N_c-2}K_{t+1}CA & \cdots & K_{t+N_c-1}CA \end{bmatrix},$$

$$G_t := \begin{bmatrix} A^{N_c-1}K_tC & A^{N_c-2}K_{t+1}C & \cdots & K_{t+N_c-1}C \end{bmatrix},$$

$$H_t := \begin{bmatrix} A^{N_c-1}K_t & A^{N_c-2}K_{t+1} & \cdots & K_{t+N_c-1} \end{bmatrix}. \text{ Using}$$

Lemma 8, we have that $\|F_t\| \leq N_c \|CA\| \|K_t\| \leq N_c \rho_m \|CA\|$, $\|G_t\| \leq N_c \|C\| \|K_t\| \leq N_c \rho_m \|C\|$, and $\|H_t\| \leq N_c \|K_t\| \leq N_c \rho_m$, for all $t \geq T'$. It follows that $\mathbb{E}_{\mathcal{Y}_t} [\|\Xi_t\|] \leq N_c \rho_m \|CA\| \mathbb{E}_{\mathcal{Y}_t} \left[\left\| \begin{matrix} e_t \\ \vdots \\ e_{t+N_c-1} \end{matrix} \right\| \right] +$

$$N_c \rho_m \|C\| \mathbb{E}_{\mathcal{Y}_t} \left[\left\| \begin{matrix} w_t \\ \vdots \\ w_{t+N_c-1} \end{matrix} \right\| \right] + N_c \rho_m \mathbb{E}_{\mathcal{Y}_t} \left[\left\| \begin{matrix} v_{t+1} \\ \vdots \\ v_{t+N_c} \end{matrix} \right\| \right]$$

$$\leq N_c^{3/2} \rho_m \left(\|CA\| \sqrt{\bar{\rho}} + \|C\| \sqrt{\text{tr}(\Sigma_w)} + \sqrt{\text{tr}(\Sigma_v)} \right) =: \zeta,$$

for all $t \geq T'$. \square

Proof of Theorem 5 We begin by showing the first claim in Theorem 5.

Lemma 9 Consider the system (1a)-(1b), and suppose that Assumption 4 holds. Then assertion (i) of Theorem 5 holds.

PROOF. *Convexity:* It is clear that $X_t^\top Q X_t + U_t^\top \mathcal{R} U_t$ is convex in X_t and U_t , and both X_t and U_t are affine functions of the design parameters $(\boldsymbol{\eta}_t, \boldsymbol{\Theta}_t)$ for every realization of the noise sequences $(w_t)_{t \in \mathbb{N}}$ and $(v_t)_{t \in \mathbb{N}}$. Since taking expectation of a convex function retains convexity [12], we conclude that the cost $V_t = \mathbb{E}_{\mathcal{Y}_t} [X_t^\top Q X_t + U_t^\top \mathcal{R} U_t]$ is convex in $(\boldsymbol{\eta}_t, \boldsymbol{\Theta}_t)$. Similarly, the constraints (17) and (22) are convex in $(\boldsymbol{\eta}_t, \boldsymbol{\Theta}_t)$ as they are a composition of convex and affine functions [12].

SOCP Formulation: Substituting the augmented dynamics (5) into the objective function (6), we have that $\mathcal{J}_t = \mathbb{E}_{\mathcal{Y}_t} [\|Ax_t + BU_t + DW_t\|_{\mathcal{Q}}^2 + \|U_t\|_{\mathcal{R}}^2] = \mathbb{E}_{\mathcal{Y}_t} [\|U_t\|_{\mathcal{M}}^2 + 2U_t^\top \mathcal{B}^\top Q (Ax_t + DW_t)] + \mathbb{E}_{\mathcal{Y}_t} [\|W_t\|_{\mathcal{D}^\top \mathcal{Q} \mathcal{D}}^2 + \|x_t\|_{\mathcal{A}^\top \mathcal{Q} \mathcal{A}}^2]$, where we have used the fact that the noise W_t is zero-mean (and $\mathcal{M} = \mathcal{R} + \mathcal{B}^\top \mathcal{Q} \mathcal{B}$). Note that the last term above does not depend on the decision variables so we shall henceforth drop it from the optimization. Now, substituting the policy (15) into the last equation and completing the square yields $\mathcal{J}_t = \mathbb{E}_{\mathcal{Y}_t} [(\boldsymbol{\eta}_t + \boldsymbol{\Theta}_t \varphi(Y_t - \hat{Y}_t))^\top \mathcal{M} (\boldsymbol{\eta}_t + \boldsymbol{\Theta}_t \varphi(Y_t - \hat{Y}_t)) + 2(\boldsymbol{\eta}_t + \boldsymbol{\Theta}_t \varphi(Y_t - \hat{Y}_t))^\top \mathcal{B}^\top Q (Ax_t + DW_t)] + \|\boldsymbol{\eta}_t + \boldsymbol{\Theta}_t \Lambda_t^\varphi\|_{\mathcal{M}}^2 + \text{tr}(\boldsymbol{\Theta}_t^\top \mathcal{M} \boldsymbol{\Theta}_t (\Lambda_t^{\varphi\varphi} - \Lambda_t^\varphi \Lambda_t^{\varphi\top})) + 2\boldsymbol{\eta}_t^\top \mathcal{B}^\top Q \mathcal{A} \hat{x}_t + 2\text{tr}(\boldsymbol{\Theta}_t^\top \mathcal{B}^\top Q (\mathcal{A} \Lambda_t^{x\varphi} + \mathcal{D} \Lambda_t^{w\varphi}))$. Note that $\Lambda_t^{\varphi\varphi} - \Lambda_t^\varphi \Lambda_t^{\varphi\top} \geq 0$, so we can further write the quadratic

term in $\boldsymbol{\Theta}_t$ in a symmetric fashion, i.e., since $\Lambda_t^{\varphi\varphi} - \Lambda_t^\varphi \Lambda_t^{\varphi\top}$ is positive semidefinite, there exists a matrix L so that $\Lambda_t^{\varphi\varphi} - \Lambda_t^\varphi \Lambda_t^{\varphi\top} = LL^\top$. It follows that $\text{tr}(\boldsymbol{\Theta}_t^\top \mathcal{M} \boldsymbol{\Theta}_t (\Lambda_t^{\varphi\varphi} - \Lambda_t^\varphi \Lambda_t^{\varphi\top})) = \text{tr}(\boldsymbol{\Theta}_t^\top \mathcal{M} \boldsymbol{\Theta}_t LL^\top) = \text{tr}(L^\top \boldsymbol{\Theta}_t^\top \mathcal{M} \boldsymbol{\Theta}_t L)$. Using the epigraph formulation gives the cost (24) and constraint (25).

Concerning the constraint (26), we have shown in [20,16] that combining the constraint $\|u_t\|_\infty \leq U_{\max}$ and the class of policies (15) is equivalent to the constraints $\|(\boldsymbol{\eta}_t)_i\| + \|(\boldsymbol{\Theta}_t)_i\|_1 \varphi_{\max} \leq U_{\max}$ for all $i = 1, \dots, Nm$. Substituting (15) into the stability constraint (22), we obtain

$$\begin{aligned} & \|A_o^{N_c} \hat{x}_t^o + \mathfrak{R}_{N_c}(A_o, B_o)(\boldsymbol{\eta}_t)_{1:N_c m} \\ & + \mathfrak{R}_{N_c}(A_o, B_o)(\boldsymbol{\Theta}_t)_{1:N_c m} \varphi(Y_t - \hat{Y}_t)\| \\ & \leq \|A_o^{N_c} \hat{x}_t^o + \mathfrak{R}_{N_c}(A_o, B_o)(\boldsymbol{\eta}_t)_{1:N_c m}\| \\ & + \|\mathfrak{R}_{N_c}(A_o, B_o)(\boldsymbol{\Theta}_t)_{1:N_c m} \varphi(Y_t - \hat{Y}_t)\| \\ & \leq \|A_o^{N_c} \hat{x}_t^o + \mathfrak{R}_{N_c}(A_o, B_o)(\boldsymbol{\eta}_t)_{1:N_c m}\| \\ & + \sqrt{n_o} \|\mathfrak{R}_{N_c}(A_o, B_o)(\boldsymbol{\Theta}_t)_{1:N_c m} \varphi(Y_t - \hat{Y}_t)\|_\infty \\ & \leq \|A_o^{N_c} \hat{x}_t^o + \mathfrak{R}_{N_c}(A_o, B_o)(\boldsymbol{\eta}_t)_{1:N_c m}\| \\ & + \sqrt{n_o} \|\mathfrak{R}_{N_c}(A_o, B_o)(\boldsymbol{\Theta}_t)_{1:N_c m}\|_\infty \varphi_{\max}. \end{aligned}$$

Enforcing that the last term above is $\leq \|\hat{x}_t^o\| - (\zeta - \frac{\varepsilon}{2})$, whenever $\|\hat{x}_t^o\| \geq \zeta + \varepsilon$, is equivalent to the constraint (27), where the decision variables are now $(z_2, z_3, \boldsymbol{\eta}_t, \boldsymbol{\Theta}_t)$. Moreover, if the constraint (27) is satisfied, then the stability constraint (22) is satisfied as well. As such, the optimization problem solved in Theorem 5-(i) is a conservative approximation of (23) due to the fact that the constraint (27) is tighter than (22). *Feasibility:* It remains to show that all the constraints are simultaneously feasible. Inspired by the work in [39], we consider the candidate controller

$$\tilde{u}_{t,t+N_c-1} = \begin{bmatrix} \eta_t \\ \vdots \\ \eta_{t+N_c-1} \end{bmatrix} = -\mathfrak{R}_{N_c}(A_o, B_o)^\dagger \text{sat}_r(A_o^{N_c} \hat{x}_t^o) \quad (38)$$

with $\eta_{t+N_c} = \eta_{t+N_c+1} = \dots = \eta_{t+N-1} = 0$ and $\boldsymbol{\Theta}_t = 0$, where $r := \zeta + \varepsilon/2$ and recall that $\text{sat}_r(v) = v$ if $\|v\| \leq r$ and $\text{sat}_r(v) = rv/\|v\|$ if $\|v\| > r$. First, we have that $\|\tilde{u}_{t,t+N_c-1}\|_\infty \leq \|\tilde{u}_{t,t+N_c-1}\|_2 \leq \sigma_{\min}(\mathfrak{R}_{N_c}(A_o, B_o))^{-1}(\zeta + \varepsilon/2) = U_{\max}^*$, and the constraint (2) is feasible. Regarding the constraint (22), we have that $\|A_o^{N_c} \hat{x}_t^o + \mathfrak{R}_{N_c}(A_o, B_o) \tilde{u}_{t,t+N_c-1}\| = \|\hat{x}_t^o\| - r \leq \|\hat{x}_t^o\| - (\zeta + \varepsilon/2)$, whenever $\|\hat{x}_t^o\| \geq \zeta + \varepsilon$, where the first equality follows from the orthogonality of A_o (see [39]), and the constraint (22) is also feasible.

Finally, it is easy to see that the cost (24) is linear and (25) through (27) are second-order cone constraints, hence the optimization program is a SOCP [4]. \square

The following result pertains to mean-square boundedness of the Schur subsystem \hat{x}_t^s of the estimator, i.e.,

$\hat{x}_{t+1}^s = A_s \hat{x}_t^s + B_s u_t + (K_t)_{1:n_s} (CA(x_t - \hat{x}_t) + Cw_t + v_{t+1})$, where $(K_t)_{1:n_s}$ are the first n_s rows of the gain K_t .

Lemma 10 *Let Assumption 1 hold. Then there exists a constant $\gamma_s > 0$, depending on the given problem parameters, such that $\mathbb{E}_{\mathcal{Y}_{T'}} [\|\hat{x}_t^s\|^2] \leq \gamma_s, \forall t \geq T'$, where T' is as defined in Proposition 3.*

PROOF. Since the matrix A_s is Schur stable, there exists a positive definite matrix $M \in \mathbb{R}^{n_s \times n_s}$ that satisfies $A_s^T M A_s - M = -I$, see [6, Proposition 11.10.5]. Pick a constant $\nu \in]0, \min\{1, 1/\lambda_{\max}(M)\}[$ such that $A_s^T M A_s - M \leq -\nu M$. Then for any $t \in \mathbb{N}$, $\mathbb{E}_{\mathcal{Y}_t} [\|\hat{x}_{t+1}^s\|_M^2] - \|\hat{x}_t^s\|_M^2 \leq -\nu \|\hat{x}_t^s\|_M^2 + 2\mathbb{E}_{\mathcal{Y}_t} [(\hat{x}_t^s)^T A_s^T M B_s u_t] + \mathbb{E}_{\mathcal{Y}_t} [\|(K_t)_{1:n_s} (CA(x_t - \hat{x}_t) + Cw_t + v_{t+1})\|_M^2]$, where $\|x\|_M^2 := x^T M x$. Using Young's inequality and Assumption 1, we have that $2\mathbb{E}_{\mathcal{Y}_t} [(\hat{x}_t^s)^T A_s^T M B_s u_t] \leq \varepsilon \mathbb{E}_{\mathcal{Y}_t} [\|A_s \hat{x}_t^s\|_M^2] + \frac{1}{\varepsilon} \mathbb{E}_{\mathcal{Y}_t} [\|B_s u_t\|_M^2] \leq \varepsilon \mathbb{E}_{\mathcal{Y}_t} [\|A_s \hat{x}_t^s\|_M^2] + \frac{m\sigma_{\max}(B_s^T M B_s)}{\varepsilon} U_{\max}^2$, for $\varepsilon > 0$ and for all $t \in \mathbb{N}$. Also, using Lemma 8 and Assumption 1, we have that $\mathbb{E}_{\mathcal{Y}_t} [\|(K_t)_{1:n_s} (CA(x_t - \hat{x}_t) + Cw_t + v_{t+1})\|_M^2] \leq 3\lambda_{\max}(M)\rho_m^2 (\|CA\|^2 \rho + \|C\|^2 \text{tr}(\Sigma_w) + \text{tr}(\Sigma_v))$. Choose an $\varepsilon \leq \frac{\nu}{2\|A_s\|_M^2}$ and let $c := \frac{m\sigma_{\max}(B_s^T M B_s)}{\varepsilon} U_{\max}^2 + 3\lambda_{\max}(M)\rho_m^2 (\|CA\|^2 \rho + \|C\|^2 \text{tr}(\Sigma_w) + \text{tr}(\Sigma_v))$, then we have $\mathbb{E}_{\mathcal{Y}_t} [\|\hat{x}_{t+1}^s\|_M^2] \leq (1 - \frac{\nu}{2}) \|\hat{x}_t^s\|_M^2 + c$, for all $t \geq T'$. Iterating the last inequality, we have $\mathbb{E}_{\mathcal{Y}_{T'}} [\|\hat{x}_t^s\|_M^2] \leq (1 - \frac{\nu}{2})^{(t-T')} \|\hat{x}_{T'}^s\|_M^2 + \sum_{i=0}^{t-T'-1} (1 - \frac{\nu}{2})^i c \leq \|\hat{x}_{T'}^s\|_M^2 + (1 - \frac{\nu}{2})^{-1} c$, for all $t \geq T'$. Setting $\gamma_s := \|\hat{x}_{T'}^s\|_M^2 + (1 - \frac{\nu}{2})^{-1} c$, completes the proof. \square

We consider next the orthogonal subsystem of the estimator and show that the process $(\hat{x}_t^o)_{t \in \mathbb{N}}$ is mean-square bounded. We shall rely on the following fundamental result pertaining to mean-square boundedness of a general random sequence $(\xi_t)_{t \in \mathbb{N}}$; it is an immediate consequence of [37, Theorem 1].

Proposition 11 *Let $(\xi_t)_{t \in \mathbb{N}}$ be a sequence of nonnegative random variables on some probability space $(\Omega, \mathfrak{F}, \mathbb{P})$, and let $(\mathfrak{F}_t)_{t \in \mathbb{N}}$ be any filtration to which $(\xi_t)_{t \in \mathbb{N}}$ is adapted. Suppose that there exist constants $\varepsilon > 0$, and $J, M < \infty$, such that $\xi_0 \leq J$, and for all $t \in \mathbb{N}$:*

$$\mathbb{E}_{\mathfrak{F}_t} [\xi_{t+1} - \xi_t] \leq -\frac{\varepsilon}{2} \quad \text{on the event } \{\xi_t > J\} \quad (39)$$

$$\text{and } \mathbb{E}_{\xi_0, \dots, \xi_t} [\xi_{t+1} - \xi_t]^4 \leq M. \quad (40)$$

Then there exists a constant $\gamma = \gamma(\varepsilon, J, M) > 0$ such that $\sup_{t \in \mathbb{N}} \mathbb{E} [\xi_t^2] \leq \gamma$.

Lemma 12 *Let Assumptions 1 and 4 hold. Then there exists a constant $\gamma_o > 0$, depending on the given problem parameters, such that*

$$\mathbb{E}_{\mathcal{Y}_T} [\|\hat{x}_t^o\|^2] \leq \gamma_o, \quad \forall t \geq T := N_c \lceil T'/\kappa \rceil. \quad (41)$$

PROOF. Consider the subsampled process

$\hat{x}_{t+N_c}^o = A_o^{N_c} \hat{x}_t^o + \mathfrak{R}_{N_c}(A_o, B_o) u_{t,t+N_c-1} + (\Xi_t)_{n-n_o+1:n}$ for $t = 0, N_c, 2N_c, \dots$, where Ξ_t is as defined in (20) and

$u_{t,t+N_c-1} := \begin{bmatrix} u_t \\ \vdots \\ u_{t+N_c-1} \end{bmatrix}$. We shall first verify the two

conditions (39) and (40) of Proposition 11 for the process $(\xi_t)_{t=0, N_c, 2N_c, \dots} = (\|\hat{x}_t^o\|)_{t=0, N_c, 2N_c, \dots}$. Using the triangle inequality, we have that $\mathbb{E}_{\mathcal{Y}_t} [\|\hat{x}_{t+N_c}^o\| - \|\hat{x}_t^o\|] \leq \mathbb{E}_{\mathcal{Y}_t} [\|A_o^{N_c} \hat{x}_t^o + \mathfrak{R}_{N_c}(A_o, B_o) u_{t,t+N_c-1}\| - \|\hat{x}_t^o\|] + \mathbb{E}_{\mathcal{Y}_t} [\|(\Xi_t)_{n-n_o+1:n}\|]$. We know from Proposition 3 that there exists a uniform (with respect to time t) upper bound ζ for the last term on the right-hand side of the last inequality for $t \geq T := N_c \lceil T'/\kappa \rceil$. Accordingly, we have $\mathbb{E}_{\mathcal{Y}_t} [\|\hat{x}_{t+N_c}^o\| - \|\hat{x}_t^o\|] \leq \mathbb{E}_{\mathcal{Y}_t} [\|A_o^{N_c} \hat{x}_t^o + \mathfrak{R}_{N_c}(A_o, B_o) u_{t,t+N_c-1}\| - \|\hat{x}_t^o\|] + \zeta \leq -\frac{\varepsilon}{2}$ whenever $\|\hat{x}_t^o\| \geq \zeta + \varepsilon$ for all $t = T, T + N_c, T + 2N_c, \dots$, where the last inequality follows from the satisfaction of the stability constraint (22); condition (39) of Proposition 11 is satisfied. By orthogonality of A_o , we have that $\|\hat{x}_t^o\| = \|A_o^{N_c} \hat{x}_t^o\|$. It follows by the triangle inequality that, for all $t = T, T + N_c, T + 2N_c, \dots$

$\mathbb{E} \{ (\|\hat{x}_i^o\|)_{i=T, T+N_c, \dots, t} \} [(\|\hat{x}_{t+N_c}^o\| - \|\hat{x}_t^o\|)^4] = \mathbb{E} \{ (\|\hat{x}_i^o\|)_{i=T, T+N_c, \dots, t} \} [(\|\hat{x}_{t+N_c}^o\| - \|A_o^{N_c} \hat{x}_t^o\|)^4] \leq \mathbb{E} \{ (\|\hat{x}_i^o\|)_{i=T, T+N_c, \dots, t} \} [(\|\mathfrak{R}_{N_c}(A_o, B_o) u_{t,t+N_c-1}\| + \|(\Xi_t)_{n-n_o+1:n}\|)^4]$. Using the inequality $(a+b)^2 \leq 2a^2 + 2b^2$, it follows that

$\mathbb{E} \{ (\|\hat{x}_i^o\|)_{i=T, T+N_c, \dots, t} \} [(\|\hat{x}_{t+N_c}^o\| - \|\hat{x}_t^o\|)^4] \leq 8\mathbb{E} \{ (\|\hat{x}_i^o\|)_{i=T, T+N_c, \dots, t} \} [\|\mathfrak{R}_{N_c}(A_o, B_o) u_{t,t+N_c-1}\|^4 + \|(\Xi_t)_{n-n_o+1:n}\|^4]$. By design $\|u_i\|_\infty \leq U_{\max}$. Also, Ξ_t is independent of $(\|\hat{x}_i^o\|)_{i=T, T+N_c, \dots, t}$, Gaussian, and has its fourth moment bounded. Therefore, there exists a constant $M > 0$ such that

$\mathbb{E} \{ (\|\hat{x}_i^o\|)_{i=T, T+N_c, \dots, t} \} [\|\mathfrak{R}_{N_c}(A_o, B_o) u_{t,t+N_c-1}\|^4 + \|(\Xi_t)_{n-n_o+1:n}\|^4] \leq M$, for all $t \geq T$. The two conditions of Proposition 11 are verified for the sequence $(\|\hat{x}_t^o\|)_{t=T, T+N_c, T+2N_c, \dots}$. Thus, by Proposition 11, there exists a constant $\gamma_o' > 0$, depending on the given problem parameters, such that $\mathbb{E}_{\mathcal{Y}_T} [\|\hat{x}_t^o\|^2] \leq \gamma_o'$, for all

$t = T, T + N_c, T + 2N_c, \dots$. Finally, using a standard argument (as in [39]) we can show the existence of another constant $\gamma_o \geq \gamma'_o$ such that the condition (41) holds. \square

PROOF. [Proof of Theorem 5] Claim (i) of Theorem 5 was proved in Lemma 9. It remains to show claim (ii). We start by asserting the following inequality $\mathbb{E}_{\mathcal{Y}_T}[\|x_t\|^2] \leq 2\mathbb{E}_{\mathcal{Y}_T}[\|x_t - \hat{x}_t\|^2] + 2\mathbb{E}_{\mathcal{Y}_T}[\|\hat{x}_t\|^2]$, for all $t \geq T = N_c \lceil T'/\kappa \rceil$. We know from Lemma 8 that $\mathbb{E}_{\mathcal{Y}_T}[\|x_t - \hat{x}_t\|^2] \leq \rho$ for all $t \geq T \geq T'$. We have that $\|\hat{x}_t\|^2 = \|\hat{x}_t^s\|^2 + \|\hat{x}_t^o\|^2$, where \hat{x}^s and \hat{x}^o are states corresponding to the Schur and orthogonal parts of the system, respectively. It then follows that $\mathbb{E}_{\mathcal{Y}_T}[\|\hat{x}_t\|^2] = \mathbb{E}_{\mathcal{Y}_T}[\|\hat{x}_t^s\|^2] + \mathbb{E}_{\mathcal{Y}_T}[\|\hat{x}_t^o\|^2]$. Using Lemmas 10 and 12 we conclude that $\mathbb{E}_{\mathcal{Y}_T}[\|\hat{x}_t\|^2] \leq \gamma_s + \gamma_o$, for all $t \geq T$, and therefore, $\mathbb{E}_{\mathcal{Y}_T}[\|x_t\|^2] \leq 2\rho + 2(\gamma_s + \gamma_o)$, for all $t \geq T$. Since the sequence $(x_t)_{t \in \mathbb{N}}$ in (1a) is generated through the addition of independent mean-square bounded random variables and a bounded control input, and since $T < \infty$, it follows that there exists a constant $\gamma > 0$ such that $\mathbb{E}_{\mathcal{Y}_0}[\|x_t\|^2] \leq \gamma$, for all $t \in \mathbb{N}$, establishing the claim (ii) of Theorem 5. \square

PROOF. [Proof of Corollary 6] The proof of Corollary 6 follows exactly the same reasoning as in the proof of Theorem 5, except for the constraints in (34) and (35). Rewriting the constraints (30) and (31) as (34) and (35), respectively, can be done similarly to the way we rewrote the cost (6) in Theorem (5). It remains to show the upper bounds α^* and β^* in (33). For the constraint (30) we have the upper-bound
$$\begin{aligned} \mathbb{E}_{\mathcal{Y}_t}[\|X_t\|_{\mathcal{S}}^2 + \mathcal{L}^T X_t] &= \mathbb{E}_{\mathcal{Y}_t}[\|\mathcal{A}x_t + \mathcal{B}U_t + \mathcal{D}W_t\|_{\mathcal{S}}^2 \\ &+ \mathcal{L}^T(\mathcal{A}x_t + \mathcal{B}U_t + \mathcal{D}W_t)] \leq 3\mathbb{E}_{\mathcal{Y}_t}[\|\mathcal{A}x_t\|_{\mathcal{S}}^2 + \|\mathcal{B}U_t\|_{\mathcal{S}}^2 \\ &+ \|\mathcal{D}W_t\|_{\mathcal{S}}^2] + \mathcal{L}^T \mathcal{A} \hat{x}_t + |\mathcal{L}^T \mathcal{B}U_t| \leq \mathcal{L}^T \mathcal{A} \hat{x}_t \\ &+ 3Nm\sigma_{\max}(\mathcal{B}^T \mathcal{S} \mathcal{B})U_{\max}^2 + \|\mathcal{L}^T \mathcal{B}\|_1 U_{\max} \\ &+ 3\text{tr}(\mathcal{A}^T \mathcal{S} \mathcal{A} \mathbb{E}_{\mathcal{Y}_t}[x_t x_t^T] + \mathcal{D}^T \mathcal{S} \mathcal{D} \Sigma_w), \end{aligned}$$
 where the first inequality follows from the fact that $(a + b + c)^2 \leq 3(a^2 + b^2 + c^2)$, for any $a, b, c > 0$, and the noise being zero-mean; the second inequality follows from applying norm bounds between the 2 and ∞ -norms and Hölder's inequality. As for the constraint (31), we have the bound
$$\mathbb{E}_{\mathcal{Y}_t}[U_t^T \tilde{\mathcal{S}} U_t] \leq \sigma_{\max}(\tilde{\mathcal{S}}) \|U_t\|^2 \leq Nm\sigma_{\max}(\tilde{\mathcal{S}}) \|U_t\|_{\infty}^2 \leq Nm\sigma_{\max}(\tilde{\mathcal{S}}) U_{\max}^2. \quad \square$$
