Abstract

The Goppa Code Distinguishing (GD) problem consists in distinguishing the matrix of a Goppa code from a random matrix. The hardness of this problem is an assumption to prove the security of code-based cryptographic primitives such as McEliece's cryptosystem. Up to now, it is widely believed that the GD problem is a hard decision problem. We present the first method allowing to distinguish alternant and Goppa codes over any field. Our technique can solve the GD problem in polynomial-time provided that the codes have sufficiently large rates. The key ingredient is an algebraic characterization of the key-recovery problem. The idea is to consider the rank of a linear system which is obtained by linearizing a particular polynomial system describing a key-recovery attack. Experimentally it appears that this dimension depends on the type of code. Explicit formulas derived from extensive experimentations for the rank are provided for "generic" random, alternant, and Goppa codes over any alphabet. Finally, we give theoretical explanations of these formulas in the case of random codes, alternant codes over any field of characteristic two and binary Goppa codes.

I. Introduction

THIS paper investigates the difficulty of the Goppa Code Distinguishing (GD) problem which first appeared in [1]. This is a decision problem that aims at recognizing a generator matrix of a binary Goppa code from a randomly drawn binary matrix. Up to now, it is assumed that no polynomial time algorithm exists that distinguishes a generator matrix of a Goppa code from a randomly picked generator matrix.

The main motivation for introducing the GD problem is to formally relate the problem of decoding a random linear code to the security of the McEliece public-key cryptosytem [2]. Since its apparition, this cryptosystem has withstood many attacks and after more than thirty years now, it still belongs to the very few unbroken public key cryptosystems. This situation substantiates the claim that inverting the encryption function, and in particular recovering the private key from public data, is intractable. The classical methods for inverting the McEliece encryption function without finding a trapdoor all resort to the use of the best general decoding algorithms [3]–[10]. All these algorithms, whose time complexity is exponential (in the length), attempt to solve the long-standing problem of decoding random linear code[11]. They also assume (implicitly or explicitly) that there does not exist an algorithm that is able to decode more efficiently McEliece public keys. Note that if ever such an algorithm exists, it would permit to solve the GD problem.

On the other hand, no significant breakthrough has been observed with respect to the problem of recovering the private key [12], [13]. This has led to state that the generator matrix of a binary Goppa code does not disclose any visible structure that an attacker could exploit. This is strengthened by the fact that Goppa codes share many characteristics with random codes. For instance they asymptotically meet the Gilbert-Varshamov bound. They also have a trivial permutation group, *etc.* Hence, the hardness of the GD problem has become a classical belief, and as a consequence, a *de facto* assumption to prove the semantic security in the standard model (IND-CPA in [14] and IND-CCA2 in [15]), and the security in the random oracle model against existential forgery [1], [16] of the signature scheme [1].

We present a deterministic polynomial-time distinguisher for codes whose rate is close to 1. This includes in particular codes encountered with the signature scheme CFS [1], [17]. However, we emphasize that our method can distinguish codes also used in McEliece's encryption scheme. For instance, the binary Goppa code obtained with $m = 13$ and $r = 19$ corresponding to a 90-bit security McEliece public key is distinguishable. More precisely, when the length of the code goes to infinity an asymptotic formula can be derived for the smallest rate R_{crit} for which we can distinguish a q-random code from a q-ary

alternant or Goppa code (Theorem 3). For a given q and assuming that the length is q^m then when m tends to infinity, we have:

$$R_{\text{crit}} = 1 - \sqrt{\frac{2\,m\,\log q}{q^m \log m}}\big(1 + o(1)\big).$$

where all logarithms are taken to base 2.

Our distinguisher is based on the algebraic attack developped against compact variants of McEliece [18]. In this approach, the key-recovery problem is transformed into the one of solving an algebraic system. By using a linearization technique, we are able to derive a linear system whose rank is different from what one would expect in the random case. More precisely, we observe experimentally that this *defect* in the rank is directly related to the type of codes. We provide explicit formulas for "generic" random, alternant, and Goppa codes over any alphabet. We performed extensive experiments to confirm that the formulas are accurate. Eventually, we prove the formula in the random case and give explanations in the case of alternant codes over any field of characteristic two and binary Goppa codes. However, the existence of our distinguisher does not undermine the security of primitives based on Goppa codes, but basically, it proves that the GD assumption is false for some parameters, and consequently should be used with great care as an assumption for a security reduction.

The paper is organized as follows. In Section III, we introduce the algebraic system that any McEliece cryptosystem must satisfy. In Section IV, we construct a linear system deduced from this algebraic system. This defines an algebraic distinguisher. We then provide explicit formulas that predicts the behavior of the distinguisher coming from experimentations. In Section VI, we give a proof of its typical behavior in the random case. In Section VII and Section VIII, we give explanations of the formulas for alternant and binary Goppa codes. Lastly, we conclude over the cryptographic implications the distinguisher induces and we deduce an asymptotic formula for the smallest rate for which we can distinguish a random code from an alternant code or a Goppa code.

II. Code-Based Public-Key Cryptography

The general problem of decoding random linear codes is a potential candidate for building public-key cryptographic primitives such as an encryption scheme. McEliece in [2] was the first to use this problem in public-key cryptography. The general idea is to start from a family of codes equipped with a polynomial-time decoding algorithm. The fundamental concept of this proposal is to consider two equivalent representations of a code: one should facilitate the decoding, whereas from the other one, the decoding should be infeasible. Although his design principle is general, he explicitly advocated to use binary Goppa codes [19].

A. Coding theory background

Code-based public-key cryptography focuses on linear codes that have a polynomial time decoding algorithm. We recall that a q-ary (linear) *code* $\mathscr{C}$ over the finite field $\mathbb{F}_q$ of q elements defined by a $k \times n$ matrix $\mathbf{G}$ (with $k \leqslant n$) whose entries belong to $\mathbb{F}_q$ is the vector space spanned by its rows *i.e.*,

$$\mathscr{C} \stackrel{\text{def}}{=} \Big\{ \mathbf{uG} \mid \mathbf{u} \in \mathbb{F}_q^k \Big\}.$$

The length of $\mathscr{C}$ is n and its rate is the ratio $R \stackrel{\text{def}}{=} k/n$. The role of decoding algorithms is to correct errors of prescribed weight. We say that a decoding algorithm corrects r errors if it recovers $\mathbf{u}$ from the knowledge of $\mathbf{uG} + \mathbf{e}$ for all possible $\mathbf{e} \in \mathbb{F}_q^n$ of weight at most r.

One famous family of codes is the one of binary Goppa codes. It belongs to the more general class of alternant codes ([20, Chap. 12, p. 365]). The main well-known feature of an alternant code is the possibility of being decoded in polynomial time. It is more convenient to describe this class through a parity-check matrix over an extension field $\mathbb{F}_{q^m}$ of $\mathbb{F}_q$ over which the code is defined. We recall that a parity-check matrix $\mathbf{H}$ of a q-ary code $\mathscr{C}$ is defined as a matrix such that:

$$\mathscr{C} \stackrel{\text{def}}{=} \Big\{ \mathbf{c} \in \mathbb{F}_q^n \mid \mathbf{Hc}^T = 0 \Big\}.$$

where the symbol ^{T} means the transpose operation. For q-ary alternant codes of length $n \leqslant q^m$, there exists a parity-check matrix with a very special form related to rectangular Vandermonde matrices:

$$\mathbf{V}_r(\mathbf{x}, \mathbf{y}) \stackrel{\text{def}}{=} \begin{pmatrix} y_1 & \cdots & y_n \\ y_1 x_1 & \cdots & y_n x_n \\ \vdots & & \vdots \\ y_1 x_1^{r-1} & \cdots & y_n x_n^{r-1} \end{pmatrix}$$

where $\mathbf{x} = (x_1, \ldots, x_n)$ and $\mathbf{y} = (y_1, \ldots, y_n)$ are in $\mathbb{F}_{q^m}^n$.

Definition 1 (Alternant code): A q-ary alternant code of order r associated to $\mathbf{x} = (x_1, \ldots, x_n) \in \mathbb{F}_{q^m}^n$ where all x_i's are distinct and $\mathbf{y} = (y_1, \ldots, y_n) \in \left(\mathbb{F}_{q^m}^*\right)^n$ denoted by $\mathscr{A}_r(\mathbf{x}, \mathbf{y})$ is $\left\{\mathbf{c} \in \mathbb{F}_q^n \mid \mathbf{V}_r(\mathbf{x}, \mathbf{y})\mathbf{c}^T = \mathbf{0}\right\}$.
It is well-known that the dimension k of an alternant codes of degree r satisfies $k \geqslant n - rm$. Moreover, a key feature about them is the following property.

Proposition 1: An alternant codes of degree r can decode in polynomial time all errors of weight at most $\frac{r}{2}$ whenever there exists a parity-check matrix in the form $\mathbf{V}_r(\mathbf{x}^*, \mathbf{y}^*)$ for some vectors $\mathbf{x}^*$ and $\mathbf{y}^*$.

Definition 2 (Goppa codes): A q-ary Goppa code $\mathscr{G}(\mathbf{x}, \Gamma)$ associated to a polynomial $\Gamma(z) \stackrel{\text{def}}{=} \sum_{i=0}^{r} \gamma_i x^i$ of degree r over $\mathbb{F}_{q^m}$ and an n-tuple $\mathbf{x} = (x_1, \ldots, x_n)$ of distinct elements of $\mathbb{F}_{q^m}$ satisfying $\Gamma(x_i) \neq 0$ for all $i, 1 \leqslant i \leqslant n$, is the q-ary alternant code $\mathscr{A}_r(\mathbf{x}, \mathbf{y})$ of order r with $y_i = \Gamma(x_i)^{-1}$.
Naturally Goppa codes, viewed as alternant codes, inherit a decoding algorithm that corrects up to $\frac{r}{2}$ errors. But in the case of *binary* Goppa codes, it is possible to correct twice as many errors. The starting point is the following result given in [20, p. 341].

Theorem 1: A binary Goppa code $\mathscr{G}(\mathbf{x}, \Gamma)$ associated to a Goppa polynomial $\Gamma(z)$ of degree r without multiple roots is equal to the alternant code $\mathscr{A}_{2r}(\mathbf{x}, \mathbf{y})$ with $y_i = \Gamma(x_i)^{-2}$.

Corollary 1 ([21]): There exists a polynomial time algorithm decoding all errors of weight at most r for any Goppa code $\mathscr{G}(\mathbf{x}, \Gamma)$ where $\Gamma(z)$ is of degree r and has no multiple roots.
It is worthwhile recalling that the only requirement for decoding a binary Goppa $\mathscr{G}$ is either to know $\mathbf{x}$ and $\Gamma(z)$ *or* to know two vectors $\mathbf{x}^*$ and $\mathbf{y}^*$ such that:

$$\mathscr{G} = \mathscr{A}_{2r}(\mathbf{x}^*, \mathbf{y}^*). \tag{1}$$

B. McEliece cryptosystem

We briefly recall here the general principle of McEliece's encryption scheme.

Secret key: the triplet $(\mathbf{S}, \mathbf{G}_s, \mathbf{P})$ of matrices defined over a finite field $\mathbb{F}_q$ over q elements, with q being a power of two, that is $q = 2^s$. $\mathbf{G}_s$ is a full rank matrix of size $k \times n$, with $k < n$, $\mathbf{S}$ is of size $k \times k$ and is invertible. $\mathbf{P}$ is a permutation matrix of size $n \times n$. The generator matrix $\mathbf{G}_s$ is chosen in such a way that its associated linear code has a decoding algorithm which corrects in polynomial time r errors.

Public key: the matrix $\mathbf{G} = \mathbf{S}\mathbf{G}_s\mathbf{P}$.

Encryption: A plaintext $\mathbf{u} \in \mathbb{F}_q^k$ is encrypted by choosing a random vector $\mathbf{e}$ in $\mathbb{F}_q^n$ of weight at most r. The corresponding ciphertext is $\mathbf{c} = \mathbf{u}\mathbf{G} + \mathbf{e}$.

Decryption: $\mathbf{c}' = \mathbf{c}\mathbf{P}^{-1}$ is computed from the ciphertext $\mathbf{c}$. Notice that $\mathbf{c}' = (\mathbf{u}\mathbf{S}\mathbf{G}_s\mathbf{P} + \mathbf{e})\mathbf{P}^{-1} = \mathbf{u}\mathbf{S}\mathbf{G}_s + \mathbf{e}\mathbf{P}^{-1}$ and that $\mathbf{e}\mathbf{P}^{-1}$ is of Hamming weight at most r. Therefore the aforementioned decoding algorithm can recover in polynomial time $\mathbf{u}\mathbf{S}$ and therefore the plaintext $\mathbf{u}$ by multiplication by $\mathbf{S}^{-1}$.

C. CFS signatures

Another important code-based cryptographic primitive is the CFS signature scheme [1]. A user whose public key is $\mathbf{G}$ and who wishes to sign a message $\mathbf{x} \in \mathbb{F}_2^k$ has to compute a string $\mathbf{u}$ such that the Hamming weight of $\mathbf{x} - \mathbf{u}\mathbf{G}$ is at most r. Anyone (a *verifier*) can publicly check the validity of a signature. Unfortunately, this approach can only provide signatures for messages $\mathbf{x}$ that are within distance r from a codeword $\mathbf{u}\mathbf{G}$. The CFS scheme prompts to modify the message by appending a counter incremented until the decoding algorithm can find such a signature. The efficiency of this scheme heavily depends on the number of trials. With a binary Goppa codes of length $n = 2^m$ and and dimension $k = n - mr$, the number of trials is of order $r!$. So one has to choose a very small r and therefore to take a very large n in order to be secure. The code rate is then equal to $\dfrac{2^m - rm}{2^m} = 1 - \dfrac{mr}{2^m}$ which is quite close to 1 for large n (that is for large values of 2^m) and moderate values of r. For instance, a 80-bit security CFS scheme requires to take $n = 2^{21}$ and $r = 10$ whereas the McEliece cryptosystem for the same security needs to choose $n = 2^{11}$ and $r = 32$ ([17]). Thus one major difference between the McEliece cryptosystem and the CFS scheme lies in the choice of the parameters.

D. Goppa Code Distinguishing Problem

The minimum requirement for an encryption function is that it should be infeasible from a given ciphertext $\mathbf{c}$ and public data[1] like the public key pk, ciphertexts, *etc.* to recover the corresponding plaintext $\mathbf{x}$. This issue is directly linked to the following computational problem.

[1]This kind of attack is called a *Chosen Plaintext Attack* (CPA).

Definition 3 (McEliece Problem): Let $\mathbf{G}$ be a generator matrix of a binary Goppa code of length $n \leqslant 2^m$ and dimension $k = n - rm$ where m and t are positive integers. Let $\mathbf{x}$ be a vector from $\mathbb{F}_{2^m}^k$ and let $\mathbf{e}$ be a vector from $\mathbb{F}_{2^m}^n$ of weight t. Finally, we set $\mathbf{c} \stackrel{\text{def}}{=} \mathbf{xG} + \mathbf{e}$. Then the *McEliece Problem* asks to find $\mathbf{x}$ and $\mathbf{e}$ only from $\mathbf{G}$ and $\mathbf{c}$.

One obvious way of solving this problem consists in devising a method that recovers the private key. But, it is also possible to recover a plaintext from a specific ciphertext without resorting to a key-recovery attack. In particular, an attacker against the McEliece scheme would find the plaintext by applying general decoding methods like [2]–[10], [22]–[26] on the public matrix $\mathbf{G}$. Such attacks are called *decoding attacks*.

The only known methods that aim to solve the McEliece problem are based either on an exhaustive search of the private key or on applying very general decoding methods. Both approaches run in exponential time on some of the parameters. But this situation is a still unsatisfactory because there is no certitude that there does not exist a better way to solve it.

A classical stance is to claim that binary Goppa codes look like random linear codes. It amounts to say that there does not exist a polynomial-time computable quantity which behaves differently depending on whether the code is a Goppa or a random code. Currently, it is an open problem to establish a formal proof that would substantiate the claim that a binary Goppa code is *indistinguishable* from a random code.

This assumption is attractive because it enables to rely on the hardness of decoding a random linear code to prove the security of the McEliece function. This reasoning does make sense because binary Goppa codes share several common aspects[2] with a randomly picked linear code. Furthermore, all the general decoding algorithms do not exploit the information, even partially, that a matrix describes a 'hidden" Goppa code. Based on this, the authors of [1] defined the *Goppa code distinguishing problem*. Before formalizing this problem, we introduce some notation. For any integers n and k such that $k \leqslant n$. We denote by $\mathsf{Goppa}(n,k)$ the set of $k \times n$ generator matrices of binary Goppa codes. Similarly, $\mathsf{Random}(n,k)$ is the set of binary $k \times n$ random generator matrices.

Definition 4 (Goppa Code Distinguishing (GD) Problem): A *distinguisher* $\mathcal{D}$ is an algorithm that takes as input a matrix $\mathbf{G}$ and returns a bit. $\mathcal{D}$ solves the GD problem if it wins the following game:

- $b \leftarrow \{0,1\}$
- If $b = 0$ then $\mathbf{G} \leftarrow \mathsf{Goppa}(n,k)$ else $\mathbf{G} \leftarrow \mathsf{Random}(n,k)$
- If $\mathcal{D}(\mathbf{G}) = b$ then $\mathcal{D}$ wins else $\mathcal{D}$ loses.

Definition 5: The advantage $Adv^{GD}(\mathcal{D})$ of a GD distinguisher $\mathcal{D}$ is defined by $Adv^{GD}(\mathcal{D}) \stackrel{\text{def}}{=}$:

$$\Big|\Pr[\mathcal{D}(\mathbf{G}) = 1 : \mathbf{G} \leftarrow \mathsf{Goppa}(n,k)] - \Pr[\mathcal{D}(\mathbf{G}) = 1 : \mathbf{G} \leftarrow \mathsf{Random}(n,k)]\Big|,$$

where $\Pr[\mathcal{D}(\mathbf{G}) = 1 : \mathbf{G} \leftarrow \mathsf{Goppa}(n,k)]$ is the probability that $\mathcal{D}$ outputs 1 when $\mathbf{G}$ is a random binary generator matrix of a Goppa code, and $\Pr[\mathcal{D}(\mathbf{G}) = 1 : \mathbf{G} \leftarrow \mathsf{Random}(n,k)]$ is defined similarly for a binary random matrix.

Definition 6: A function $\varepsilon(k)$ is *negligible* if for any integer $a > 0$, there exists an integer $k_a > 0$ such that:

$$\forall k \geqslant k_a, \quad \varepsilon(k) < \frac{1}{k^a}.$$

The interest of negligible function is to keep a probability of an event negligible even after polynomially many tries. We are now able to state an important assumption[3].

Assumption 1 ([1]): $Adv^{GD}(\mathcal{D})$ is negligible for any polynomial-time algorithm $\mathcal{D}$ that solves the GD problem.

Until our recent work in [27] and this paper, the only known algorithm that solves the GD problem enumerates binary Goppa codes and tests the code equivalence thanks to the *Support Splitting* algorithm [28]. This approach runs in time $\mathcal{O}(\frac{n^{r-1}}{mr})$ for binary Goppa codes of degree r and length n with $m \leqslant \log_2 n$ and $r = \frac{1}{m}(1-R)n$ where R is the code rate.

E. Semantically Secure Conversions

The fundamental issue when dealing with cryptographic primitives is to prove its security. Several approaches are possible. The most natural one is to show that the primitive resists to the best known attacks. However, this does not guarantee that there will not appear one day a better attack that renders the primitive insecure. The methodology of *security proof by reduction* appeared to remedy this question by linking a security notion that a cryptographic primitive should verify to an algorithmic problem widely considered as hard. The approach is similar to the one that proves the NP-Completeness of a given problem. Such a "security proof" proves that if an attacker exists then it can be used as a subroutine to solve a hard problem. In other words, such an attacker has little chances to exist.

[2]Similarly to random codes, Goppa codes asymptotically meet the Gilbert-Varshamov bound. They have also a trivial permutation group like random codes.

[3]According to [1], proving or disproving the hardness of the GD problem will have a significant impact: *"Classification issues are in the core of coding theory since its emergence in the 50's. So far nothing significant is known about Goppa codes, more precisely there is no known property invariant by permutation and computable in polynomial time which characterizes Goppa codes. Finding such a property or proving that none exists would be an important breakthrough in coding theory and would also probably seal the fate, for good or ill, of Goppa code-based cryptosystems".*

These simple facts prompt to design conversions that would lead to an IND-CCA secure encryption scheme. The first article to propose such a conversion for the McEliece cryptosystem is [29] which proposes a conversion resulting into an IND-CCA2 in the *Random Oracle Model* under the assumption that the problem of decoding random linear codes is difficult. This work was then followed by [30] which proposes another modification while providing an IND-CPA secure encryption scheme in the standard model[4] under the assumptions that both decoding random linear codes *and* distinguishing Goppa codes are difficult problems. Finally, under the same assumptions, [31] proposed (a modified) McEliece cryptosystem that is IND-CCA2 in the *standard model*.

III. Algebraic Cryptanalysis of McEliece-like Cryptosystems

The McEliece cryptosystem relies on binary Goppa codes which belong to the class of *alternant codes*. We are now able to construct an algebraic system as explained in [18] for a key-recovey. This algebraic system will be the main ingredient for building a distinguisher. We assume that the public matrix is a $k \times n$ generator matrix $\mathbf{G}$ where by assumption $k = n - rm$. We know that the knowledge of a matrix $\mathbf{V}_r(\mathbf{x}^*, \mathbf{y}^*)$ for some vectors $\mathbf{x}^*$ and $\mathbf{y}^*$ allows to efficiently decode the public code defined by $\mathbf{G}$. Furthermore, from the definition of $\mathbf{G}$, we also know that:

$$\mathbf{V}_r(\mathbf{x}^*, \mathbf{y}^*)\mathbf{G}^T = \mathbf{0}.$$

Let $X_1, \ldots, X_n$ and $Y_1, \ldots, Y_n$ be $2n$ variables corresponding to the x_i^*'s and the y_i^*'s. Observe that such x_i^*'s and y_i^*'s are a particular solution [18] of the following polynomial system:

$$\left\{ g_{i,1}Y_1X_1^j + \cdots + g_{i,n}Y_nX_n^j = 0 \mid 1 \leqslant i \leqslant k \text{ and } 0 \leqslant j \leqslant r-1 \right\} \tag{2}$$

where the $g_{i,j}$'s are the entries of the known matrix $\mathbf{G}$.

Clearly, solving this system would lead to a possibly equivalent private key. For compact variants [32], [33] of [2], additional structures permit to drastically reduce the number of variables allowing to solve (2) for a large set of parameters in polynomial-time using dedicated Gröbner bases techniques [18]. But the general case is currently a major *open question*. However, we describe a simple way for *partially* solving (2). It basically consists in deriving a linear system from the polynomial system (2). Note that this operation is actually the first step performed during the computation of Gröbner bases algorithms such as by F4 or F5 [34], [35]. From now on, we will always assume that $q = 2^s$ with $s \geqslant 1$.We can assume that $\mathbf{G} = (g_{ij})$ with $1 \leqslant i \leqslant k$ and $1 \leqslant j \leqslant n$ is in reduced row echelon form over its k first positions:

$$\mathbf{G} = (\mathbf{I}_k \mid \mathbf{P})$$

where $\mathbf{P} = (p_{ij})$ for $1 \leqslant i \leqslant k$ and $k+1 \leqslant j \leqslant n$ is the submatrix of $\mathbf{G}$ formed by its last $n - k = mr$ columns. Next, for any $i \in \{1, \ldots, k\}$ and $e \in \{0, \ldots, r-1\}$, we can rewrite (2) as

$$Y_iX_i^e = \sum_{j=k+1}^{n} p_{i,j}Y_jX_j^e. \tag{3}$$

In particular, it follows that for all i in $\{1, \ldots, k\}$:

$$\begin{cases} Y_i & = & \displaystyle\sum_{j=k+1}^{n} p_{i,j}Y_j \\ Y_iX_i & = & \displaystyle\sum_{j=k+1}^{n} p_{i,j}Y_jX_j \\ Y_iX_i^2 & = & \displaystyle\sum_{j=k+1}^{n} p_{i,j}Y_jX_j^2. \end{cases}$$

Then, thanks to the trivial identity $Y_i(Y_iX_i^2) = (Y_iX_i)^2$ for all i in $\{1, \ldots, k\}$, we get:

$$\sum_{j=k+1}^{n} p_{i,j}Y_j \sum_{j=k+1}^{n} p_{i,j}Y_jX_j^2 = \left(\sum_{j=k+1}^{n} p_{i,j}Y_jX_j \right)^2.$$

It is possible to reorder this to obtain:

$$\sum_{j=k+1}^{n-1} \sum_{j'>j}^{n} p_{i,j}p_{i,j'} \left(Y_jY_{j'}X_{j'}^2 + Y_{j'}Y_jX_j^2 \right) = 0.$$

[4]There is no hash function in this model

We thus obtain a linear system $\mathcal{L}_{\mathbf{P}}$ of k equations involving $\binom{mr}{2}$ variables $Z_{jj'} \stackrel{\text{def}}{=} Y_j Y_{j'} X_{j'}^2 + Y_{j'} Y_j X_j^2$

$$\mathcal{L}_{\mathbf{P}} \stackrel{\text{def}}{=} \begin{cases} \sum_{j=k+1}^{n-1} \sum_{j'>j}^{n} p_{1,j} p_{i,j'} Z_{jj'} = 0 \\ \qquad\qquad \vdots \\ \sum_{j=k+1}^{n-1} \sum_{j'>j}^{n} p_{k,j} p_{i,j'} Z_{jj'} = 0 \end{cases} \tag{4}$$

Definition 7: For any integer $r \geqslant 1$ and $m \geqslant 1$, the number of variables $\binom{mr}{2}$ in the linear system $\mathcal{L}_{\mathbf{P}}$ as defined in (4) is denoted by N and its rank by $\mathtt{rank}(\mathcal{L}_{\mathbf{P}})$. We denote by $\mathtt{Ker}(\mathcal{L}_{\mathbf{P}})$ the kernel of $\mathcal{L}_{\mathbf{P}}$ and its dimension as a $\mathbb{F}_q$-vector space is denoted by D.

Let us recall that $\mathtt{Ker}(\mathcal{L}_{\mathbf{P}})$ is necessarily a $\mathbb{F}_q$-vector space since the linear system (4) have coefficients in $\mathbb{F}_q$ but the solutions of (2) are sought in the extension field $\mathbb{F}_{q^m}$. Furthermore, we obviously have:

$$D = N - \mathtt{rank}(\mathcal{L}_{\mathbf{P}}).$$

Hence, in order to recover the solutions of (2), it is necessary that $\mathtt{rank}(\mathcal{L}_{\mathbf{P}})$ is almost equal to the number of variables $N = \binom{mr}{2}$. For a random system, this is likely to happen when the number k of equations in (4) is greater than the number of unknowns, that is to say:

$$k \geqslant N.$$

It appears experimentally that D is amazingly *large even in the case where* $k \geqslant N$. It even depends on whether or not the code with generator matrix $\mathbf{G}$ is chosen as a (generic) alternant code or as a Goppa code. Interestingly enough, when $\mathbf{G}$ is chosen at random, $\mathtt{rank}(\mathcal{L}_{\mathbf{P}})$ is equal to $\min\{k, N\}$ with very high probability. In particular, the dimension of the solution space is typically 0 when k is larger than the number of variables N as one would expect. This will be proved in Section VI. Although this *defect* in the rank is an obstacle to break the McEliece cryptosystem, it can be used to distinguish the public generator of a *structured* code from a random code.

IV. A Distinguisher of Alternant and Goppa Codes

We consider three cases: when the p_{ij}'s are chosen uniformly and independently at random in $\mathbb{F}_q$ then we denote by D_{random} the dimension of $\mathtt{Ker}(\mathcal{L}_{\mathbf{P}})$. When $\mathbf{G}$ is chosen as a generator matrix of a random alternant (*resp.* Goppa) code of degree r, we denote it by $D_{\text{alternant}}$ (*resp.* D_{Goppa}). We carried out intensive computations with Magma [36] by randomly generating alternant and Goppa codes over the field $\mathbb{F}_q$ with $q \in \{2, 4, 8, 16, 32\}$ for r in the range $\{3, \ldots, 50\}$ and several values of m. Furthermore, in our probabilistic model, a random alternant code is obtained by picking uniformly and independently at random two vectors $(x_1, \ldots, x_n)$ and $(y_1, \ldots, y_n)$ from $(\mathbb{F}_{q^m})^n$ such that the x_i's are all different and the y_i's are all nonzero. A random Goppa code is obtained by taking a random vector $(x_1, \ldots, x_n)$ in $(\mathbb{F}_{q^m})^n$ with all the x_i's different and a random *irreducible* polynomial $\Gamma(z) = \sum_i \gamma_i z^i$ of degree r. Our experiments have revealed that the dimension of $\mathtt{Ker}(\mathcal{L}_{\mathbf{P}})$ is *predictable* and follows formulas.

Experimental Fact 1 (Alternant Case): As long as

$$N - D_{\text{alternant}} < k,$$

then with high probability, $D_{\text{alternant}}$ is equal to $T_{\text{alternant}}$ where:

$$T_{\text{alternant}} \stackrel{\text{def}}{=} \frac{1}{2} m(r-1) \left((2e+1)r - 2\frac{q^{e+1}-1}{q-1} \right) \tag{5}$$

where $e \stackrel{\text{def}}{=} \lfloor \log_q(r-1) \rfloor$.

Experimental Fact 2 (Goppa Case): As long as

$$N - D_{\text{Goppa}} < k,$$

then with high probability, D_{Goppa} is equal to T_{Goppa} where:

$$T_{\text{Goppa}} \stackrel{\text{def}}{=} \begin{cases} \frac{1}{2} m(r-1)(r-2) = T_{\text{alternant}} \text{ for } r < q-1, \\ \\ \frac{1}{2} mr\Big((2e+1)r - 2q^e + 2q^{e-1} - 1 \Big) \text{ for } r \geqslant q-1, \end{cases} \tag{6}$$

with e being the unique integer such that:

$$(q-1)^2 q^{e-2} < r \leqslant (q-1)^2 q^{e-1}.$$

V. Experimental Results

We gathered in Table II-XI in the appendix some samples of the results obtained through intensive computations with the Magma system [36]. We randomly generated alternant and Goppa codes over the field $\mathbb{F}_q$ with $q \in \{2, 4, 8, 16, 32\}$ for values of r in the range $\{3, \ldots, 50\}$ and several m. The Goppa codes are generated by means of an irreducible $\Gamma(z)$ of degree r and hence $\Gamma(z)$ has no multiple roots. In particular, we can apply Theorem 1 in the binary case. We compare the dimensions of the solution space against the dimension D_{random} of the system derived from a random linear code. Table II and Table III give figures for the binary case with $m = 14$. We can check that D_{random} is equal to 0 for $r \in \{3, \ldots, 12\}$ and $D_{\text{random}} = N - k$ as expected. We remark that $D_{\text{alternant}}$ is different from D_{random} whenever $r \leqslant 15$, and D_{Goppa} is different from D_{random} as long as $r \leqslant 25$. Finally we observe that our formulas for $T_{\mathsf{alternant}}$ fit as long as $k \geqslant N - D_{\text{alternant}}$ which correspond to $r \leqslant 15$. This is also the case for binary Goppa codes since we have $T_{\mathsf{Goppa}} = D_{\text{Goppa}}$ as long as $k \geqslant N - D_{\text{Goppa}}$ *i.e.,* $r \leqslant 25$. We also give in Table X and Table XI the examples we obtained for $q = 4$ and $m = 6$ to check that the arguments also apply. We also compare binary Goppa codes and random linear codes for $m = 15$ in Table IV-VI and $m = 16$ in Table VII-IX. We see that D_{random} and D_{Goppa} are different for $r \leqslant 33$ when $m = 15$ and for $m = 16$ they are different even beyond our range of experiment ($r \leqslant 50$).

VI. Random Case

The purpose of this section is to study the behavior of D_{random}, namely the dimension of $\mathtt{Ker}(\mathcal{L}_{\mathbf{P}})$ as $\mathbb{F}_q$-vector space when the entries of the matrix P are drawn independently from the uniform distribution over $\mathbb{F}_q$. In this case, we can show that:

Theorem 2: Assume that $N \leqslant k$ and that the entries of P are drawn independently from the uniform distribution over $\mathbb{F}_q$. Then for any function $\omega(x)$ tending to infinity as x goes to infinity, we have

$$\mathbf{prob}\Big(D_{\text{random}} \geqslant mr\omega(mr)\Big) = o(1),$$

as mr goes to infinity.

Notice that if we choose $\omega(x) = \log(x)$ for instance, then asymptotically the dimension D_{random} of the solution space is with very large probability smaller than $mr\log(mr)$. When m and r are of the same order (which is generally chosen in practice) this quantity is smaller than $D_{\text{alternant}}$ or D_{Goppa} which are of the form $\Omega(mr^2)$.

The main ingredient for proving Theorem 2 consists in analyzing a certain (partial) Gaussian elimination process on the matrix:

$$M \stackrel{\text{def}}{=} \Big(p_{ij}p_{ij'}\Big)_{\substack{1\leqslant i\leqslant k \\ k+1\leqslant j<j'\leqslant n}}.$$

We can see the matrix M in block form, each block consists of the matrix:

$$B_j = \Big(p_{i,k+j}p_{i,k+j'}\Big)_{\substack{1\leqslant i\leqslant k \\ 1\leqslant j<j'\leqslant n-k}}.$$

Each block B_j is of size $k \times (rm - j)$. Notice that in B_j, the rows for which $p_{i,k+j} = 0$ consist only of zeros. To start the Gaussian elimination process with B_1, we will therefore choose $rm-1$ rows for which $p_{i,k+1} \neq 0$. This gives a square matrix M_1. We perform Gaussian elimination on M by adding rows involved in M_1 to put the first block B_1 in standard form. We continue this process with B_2 by picking now $rm - 2$ rows which have not been chosen before and which correspond to $p_{i,k+2} \neq 0$. This yields a square submatrix M_2 of size $rm - 2$ and we continue this process until we reach the last block. The key observation is that:

$$\mathtt{rank}(M) \geqslant \mathtt{rank}(M_1) + \cdots + \mathtt{rank}(M_{rm-1}).$$

A rough analysis of this process yields Theorem 2. The important point is that what happens for different blocks are independent processes and it corresponds to looking at different rows of the matrix P. We give all the previous results that we need in order to prove Theorem 2.

It will be convenient to assume that the columns of M are ordered lexicographically. The index of the first column is $(j, j') = (k + 1, k + 2)$, the second one is $(j, j') = (k + 1, k + 3)$, while the last one is $(j, j') = (n - 1, n)$. The matrices M_i's which are involved in the Gaussian elimination process mentioned above are defined inductively as follows. Let E_1 be the subset of $\{1, \ldots, k\}$ of indices s such that $p_{s,k+1} \neq 0$. Let F_1 be the subset of E_1 formed by its first $rm - 1$ elements (if these elements exist). Now , we set

$$M_1 \stackrel{\text{def}}{=} (p_{s,k+1}p_{s,j})_{\substack{s\in F_1 \\ k+1<j\leqslant n}}. \tag{7}$$

Let r_1 be the rank of M_1. To simplify the discussion, we assume that:

1) $F_1 = \{1, 2, \ldots, rm - 1\}$,
2) the submatrix N_1 of M_1 formed by its first r_1 rows and columns is of full rank.

Note that we can always assume this by performing suitable row and column permutations. In other words M has the following block structure:

$$M = \begin{pmatrix} N_1 & B_1 \\ A_1 & C_1 \end{pmatrix}.$$

We denote:

$$M^{(1)} \stackrel{\text{def}}{=} \begin{pmatrix} N_1^{-1} & O \\ -A_1 N_1^{-1} & I \end{pmatrix} M,$$

where O is a matrix of size $r_1 \times (k - r_1)$ with only zero entries and I is the identity matrix of size $k - r_1$. Notice that $M^{(1)}$ takes the block form:

$$M^{(1)} = \begin{pmatrix} I & B_1' \\ O & C_1' \end{pmatrix}.$$

This is basically performing Gaussian elimination on M in order to have the first r_1 columns in standard form. We then define inductively the $E_i, F_i, M_i, M^{(i)}$ and N_i as follows:

$$\begin{aligned} E_i &\stackrel{\text{def}}{=} \left\{ s \mid 1 \leqslant s \leqslant k, p_{s,k+i} \neq 0 \right\} \setminus \bigcup_{u=1}^{i-1} F_{i-u}, \\ F_i &\stackrel{\text{def}}{=} \text{the first } rm - i \text{ elements of } E_i. \end{aligned}$$

M_i is the submatrix of $M^{(i-1)}$ obtained from the rows in F_i and the columns associated to the indices of the form $(k+i, j')$ where j' ranges from $k+i+1$ to n. $M^{(i)}$ is obtained from $M^{(i-1)}$ by first choosing a square submatrix N_i of M_i of full rank and with the same rank as M_i and then by performing Gaussian elimination on the rows in order to put the columns of $M^{(i-1)}$ involved in N_i in standard form (i.e., the submatrix of $M^{(i-1)}$ corresponding to N_i becomes the identity matrix while the other entries in the columns involved in N_i become zero). It is clear that the whole process leading to $M^{(rm-1)}$ amounts to perform (partial) Gaussian elimination to M. Hence:

Lemma 1: When $|E_i| \geqslant rm - i$, for all $i \in \{1, \ldots, rm-1\}$, we have:

$$\texttt{rank}(M) \geqslant \sum_{i=1}^{rm-1} \texttt{rank}(M_i).$$

Another observation is that M_i is equal to the sum of the submatrix $(p_{s,k+i}p_{s,j})_{\substack{s \in F_i \\ k+i<j \leqslant n}}$ of M and a certain matrix which is some function on the entries $p_{t,k+i}p_{t,j}$ where t belongs to $F_1 \cup \ldots F_{i-1}$ and j ranges over $\{k+i+1, n\}$. Since by definition of F_i, $p_{s,k+i}$ is different from 0 for s in F_i. In addition, the rank of M_i does not change by multiplying each row of index s by $p_{s,k+i}^{-1}$. Then, it turns out that the rank of M_i is equal to the rank of a matrix which is the sum of the matrix $(p_{s,j})_{\substack{s \in F_i \\ k+i<j \leqslant n}}$, another matrix depending on the $p_{t,k+i}p_{t,j}$'s (where t ranges over $F_1 \cup \ldots F_{i-1}$) and the $p_{s,k+1}$'s with $s \in F_i$. This proves that:

Lemma 2: Assume that $|E_i| \geqslant rm - i$ for all $i \in \{1, \ldots, rm-1\}$. Then, the random variables $\texttt{rank}(M_i)$ are independent and $\texttt{rank}(M_i)$ is distributed as the rank of a square matrix of size $rm - i$ with entries drawn independently from the uniform distribution on $\mathbb{F}_q$.

Another essential ingredient for proving Theorem 2 is the following well known lemma (see for instance [37][Theorem 1])

Lemma 3: There exist two positive constants A and B depending on q such that the probability $p(s, \ell)$ that a random $\ell \times \ell$ matrix over $\mathbb{F}_q$ is of rank $\ell - s$ (where the coefficients are drawn independently from each other from the uniform distribution on $\mathbb{F}_q$) satisfies

$$\frac{A}{q^{s^2}} \leqslant p(s, \ell) \leqslant \frac{B}{q^{s^2}}.$$

This enables to control the exponential moments of the defect of a random matrix. For a square matrix M of size $\ell \times \ell$, we define the defect $d(M)$ by $d(M) \stackrel{\text{def}}{=} \ell - \texttt{rank}(M)$.

Lemma 4: If M is random square matrix whose entries are drawn independently from the uniform distribution over $\mathbb{F}_q$, then there exists some constant K such that for every $\lambda > 0$,

$$\mathbb{E}\left(q^{\lambda d(\mathbf{M})}\right) \leqslant K q^{\frac{\lambda^2}{4}},$$

$\mathbb{E}(.)$ denoting the expectation.

Proof: By using Lemma 3, we obtain:

$$\mathbb{E}\left(q^{\lambda d(M)}\right) \leqslant \sum_{d=0}^{\infty} q^{\lambda d} \frac{B}{q^{d^2}} \leqslant B \sum_{d=0}^{\infty} q^{\lambda d - d^2}.$$

Observe that the maximum of the function $d \mapsto q^{\lambda d - d^2}$ is reached for $d_0 = \frac{\lambda}{2}$ and is equal to $q^{\frac{\lambda^2}{4}}$. Then, we can write the sum above as:

$$\sum_{d=0}^{\infty} q^{\lambda d - d^2} = \sum_{d \leqslant d_0} q^{\lambda d - d^2} + \sum_{d > d_0} q^{\lambda d - d^2}$$

Finally, we notice that:

$$\begin{aligned} \frac{q^{\lambda(d+1)-(d+1)^2}}{q^{\lambda d - d^2}} &\leqslant \frac{q^{\lambda(d_0+1)-(d_0+1)^2}}{q^{\lambda d_0 - d_0^2}} = \frac{1}{q} \text{ for } d > d_0, \\ \frac{q^{\lambda(d-1)-(d-1)^2}}{q^{\lambda d - d^2}} &\leqslant \frac{q^{\lambda(d_0-1)-(d_0-1)^2}}{q^{\lambda d_0 - d_0^2}} = \frac{1}{q} \text{ for } d \leqslant d_0. \end{aligned}$$

This leads to:

$$\begin{aligned} \sum_{d=0}^{\infty} q^{\lambda d - d^2} &\leqslant \sum_{d \leqslant d_0} q^{d - \lfloor d_0 \rfloor} q^{\frac{\lambda^2}{4}} + \sum_{d > d_0} q^{\lceil d_0 \rceil - d} q^{\frac{\lambda^2}{4}} \\ &= O\left(q^{\frac{\lambda^2}{4}}\right). \end{aligned}$$

■

We can use now the previous lemma together with Lemma 1 and Lemma 2 to derive the following lemma.

Lemma 5: Assuming that $|E_i| \geqslant rm - i$ for all $i \in \{1, \ldots, t\}$, we get:

$$\mathbf{prob}\left(\sum_{i=1}^{t} d(M_i) \geqslant u\right) \leqslant K^t q^{-\frac{u^2}{t}}$$

where K is the constant appearing in Lemma 4.

Proof: Let $D \stackrel{\text{def}}{=} \sum_{i=1}^{t} d(\mathbf{M}_i)$. Using Markov's inequality:

$$\mathbf{prob}(D \geqslant u) \leqslant \frac{\mathbb{E}(q^{\lambda D})}{q^{\lambda u}} \tag{8}$$

for some well chosen $\lambda > 0$. The exponential moment appearing at the numerator is upper-bounded with the help of the previous lemma and by using the independence of the random variables $q^{\lambda d(\mathbf{M}_i)}$, i.e.,:

$$\begin{aligned} \mathbb{E}(q^{\lambda D}) &= \mathbb{E}\left(q^{\lambda \sum_{i=1}^{t} d(M_i)}\right) \\ &= \prod_{i=1}^{t} \mathbb{E}\left(q^{\lambda d(\mathbf{M}_i)}\right) \\ &\leqslant K^t q^{\frac{t\lambda^2}{4}}. \end{aligned} \tag{9}$$

Using now (9) in (8), we obtain

$$\mathbf{prob}(D \geqslant \alpha t) \leqslant K^t \frac{q^{\frac{t\lambda^2}{4}}}{q^{\lambda u}} = K^t q^{\frac{t\lambda^2}{4} - \lambda u}.$$

We choose $\lambda = \frac{2u}{t}$ to minimize this upper-bound, leading to:

$$\mathbf{prob}(D \geqslant u) \leqslant K^t q^{-\frac{u^2}{t}}.$$

■

The last ingredient for proving Theorem 2 is a bound on the probability that E_i is too small to construct F_i.

Lemma 6: Let $u_i \stackrel{\text{def}}{=} \binom{mr}{2} - \frac{(2rm-i)(i-1)}{2}$ and F be the event "$|F_j| = rm - j$ for $j \in \{1, \ldots, i-1\}$" then

$$\mathbf{prob}\left(|E_i| < rm - i \mid \ F\right) \leqslant e^{-2\frac{\left(\frac{q-1}{q} u_i - rm - i + 1\right)^2}{u_i}}.$$

Proof: When all the sets F_j are of size $rm - j$ for j in $\{1, \ldots, i-1\}$, it remains

$$N - \sum_{j=1}^{i-1} (rm - j) = N - \frac{(2rm-i)(i-1)}{2} = u_i$$

rows which can be picked up for E_i. Let S_t be the sum of t Bernoulli variables of parameter $\frac{q-1}{q}$. We obviously have

$$\mathbf{prob}(|E_i| < rm - i \mid \ F) = \mathbf{prob}(S_{u_i} < rm - i).$$

It remains to use the Hoeffding inequality on the binomial tails to finish the proof. ∎

We are ready now to prove Theorem 2:

Proof of Theorem 2: Let $u = \lceil \sqrt{mr\omega(mr)} \rceil$. We observe now that if all E_j's are of size at least $rm-j$ for $j \in \{1, \ldots, u\}$, we can write

$$\begin{aligned} D &= N - \mathtt{rank}(M) \\ &\leqslant N - \sum_{i=1}^{rm-u} \mathtt{rank}(M_i) \text{ (by Lemma 1)} \\ &= \sum_{i=1}^{rm-1} (rm-i) - \sum_{i=1}^{rm-u} \mathtt{rank}(M_i) \\ &= \sum_{i=1}^{rm-u} d(M_i) + \sum_{i=rm-u+1}^{rm-1} (rm-i) \\ &= \sum_{i=1}^{rm-u} d(M_i) + \frac{u(u-1)}{2} \\ &< \sum_{i=1}^{rm-u} d(M_i) + \frac{mr\omega(mr)}{2}. \end{aligned}$$

From this we deduce that

$$\begin{aligned} \mathbf{prob}\big(D_{\text{random}} \geqslant mr\omega(mr)\big) &\leqslant \mathbf{prob}(A \cup B) \\ &\leqslant \mathbf{prob}(A) + \mathbf{prob}(B) \end{aligned}$$

where A is the event "$\sum_{i=1}^{rm-u} d(M_i) \geqslant \frac{mr\omega(mr)}{2}$" and B is the event "for at least one E_j with $j \in \{1, \ldots, rm-u\}$ we have $|E_j| < rm - j$". We use now Lemma 5 to prove that $\mathbf{prob}(A) = o(1)$ as rm goes to infinity. We finish the proof by noticing that the probability of the complementary set of B satisfies

$$\begin{aligned} \mathbf{prob}(\bar{B}) &= \mathbf{prob}\left(\bigcap_{i=1}^{rm-u} |E_i| \geqslant rm - i \right) \\ &= \prod_{i=1}^{rm-u} \mathbf{prob}\left(|E_i| \geqslant rm - i \mid \ F \right) \\ &= 1 - o(1) \text{ (by Lemma 6).} \end{aligned}$$

∎

VII. Alternant Case

The goal of this section is to explain the value of the dimension $D_{\text{alternant}}$ of $\mathtt{Ker}(\mathcal{L}_{\mathbf{P}})$ for q-ary alternant codes of degree r. We shall see that this dimension will be obtained by first identifying a $\mathbb{F}_{q^m}$-basis of $\mathtt{Ker}(\mathcal{L}_{\mathbf{P}})$ when viewed as a linear system with coefficients in $\mathbb{F}_{q^m}$. To set up the linear system $\mathcal{L}_{\mathbf{P}}$ as defined in (4), we have used the trivial identity $Y_i Y_i X_i^2 = (Y_i X_i)^2$. The fundamental remark is that we can use any identity $Y_i X_i^a Y_i X_i^b = Y_i X_i^c Y_i X_i^d$ with $a, b, c, d \in \{0, 1, \ldots, r-1\}$ such that $a + b = c + d$. Such identities lead to the same algebraic system $\mathcal{L}_{\mathbf{P}}$:

$$\sum_{(j,j') \in J} p_{i,j} p_{i,j'} \left(Y_j X_j^a Y_{j'} X_{j'}^b + Y_{j'} X_{j'}^a Y_j X_j^b + Y_j X_j^c Y_{j'} X_{j'}^d + Y_{j'} X_{j'}^c Y_j X_j^d \right) = 0 \tag{10}$$

where by definition

$$J \stackrel{\text{def}}{=} \Big\{ (j, j') \in \mathbb{N} \times \mathbb{N} \mid k+1 \leqslant j < j' \leqslant n \Big\}. \tag{11}$$

Consequently, the fact that *there are many different ways of combining the equations of the algebraic system together yielding the same linearized system* $\mathcal{L}_{\mathbf{P}}$ explains why the dimension $\mathtt{Ker}(\mathcal{L}_{\mathbf{P}})$ is large. Indeed, if a non-trivial solution of $X_1, \ldots, X_n, Y_1, \ldots, Y_n$ exists then all the expressions of the form

$$Y_j X_j^a Y_{j'} X_{j'}^b + Y_{j'} X_{j'}^a Y_j X_j^b + Y_j X_j^c Y_{j'} X_{j'}^d + Y_{j'} X_{j'}^c Y_j X_j^d$$

for all $(j, j') \in J$, and for all $a, b, c, d \in \{0, 1, \ldots, r-1\}$ such that $a + b = c + d$ lead to a solution of the linear system $\mathcal{L}_{\mathbf{P}}$.

In what follows, we exhibit further elements of $\mathtt{Ker}(\mathcal{L}_{\mathbf{P}})$. To this end, we use the automorphisms $x \longmapsto x^{q^\ell}$ where ℓ is in $\{0, \ldots, m-1\}$. Indeed, we can also consider the identity:

$$(Y_i X_i^a)^{q^{\ell'}} (Y_i X_i^b)^{q^\ell} = (Y_i X_i^c)^{q^{\ell'}} (Y_i X_i^d)^{q^\ell} \tag{12}$$

for any integers a, b, c, d, ℓ and ℓ' such that:

$$aq^{\ell'} + bq^{\ell} = cq^{\ell'} + dq^{\ell}.$$

We get again the linear system $\mathcal{L}_{\mathbf{P}}$. However, assuming that $\ell' \leqslant \ell$, solutions obtained from such equations are exactly those coming from the identity:

$$Y_i X_i^a Y_i^{q^{\ell-\ell'}} X_i^{bq^{\ell-\ell'}} = Y_i X_i^c Y_i^{q^{\ell-\ell'}} X_i^{dq^{\ell-\ell'}}. \tag{13}$$

We can focus on vectors that satisfy equations obtained with $0 \leqslant a, b, c, d < r, 0 \leqslant \ell < m$ and $a + q^{\ell} b = c + q^{\ell} d$ *i.e.*, the equations obtained from:

$$Y_i X_i^a (Y_i X_i^b)^{q^{\ell}} = Y_i X_i^c (Y_i X_i^d)^{q^{\ell}}.$$

We now try to determine the number of linearly independent solutions induced by such identities.

Definition 8: Let a, b, c and d be integers in $\{0, \ldots, r-1\}$ and an integer ℓ in $\{0, \ldots, m-1\}$ such that $a + q^{\ell} b = c + q^{\ell} d$. We define $\mathbf{U}^{a,b,c,d,\ell} = \left(\mathbf{U}_{j,j'}^{a,b,c,d,\ell}\right)_{(j,j') \in J}$ with

$$\mathbf{U}_{j,j'}^{a,b,c,d,\ell} \stackrel{\text{def}}{=} Y_j X_j^a Y_{j'}^{q^{\ell}} X_{j'}^{q^{\ell} b} + Y_j X_j^c Y_{j'}^{q^{\ell}} X_{j'}^{q^{\ell} d}.$$

In the same way, we set $\overline{\mathbf{U}}^{a,b,c,d,\ell} = \left(\overline{\mathbf{U}}_{j,j'}^{a,b,c,d,\ell}\right)_{(j,j') \in J}$ where

$$\overline{\mathbf{U}}_{j,j'}^{a,b,c,d,\ell} \stackrel{\text{def}}{=} Y_{j'} X_{j'}^a Y_j^{q^{\ell}} X_j^{q^{\ell} b} + Y_{j'} X_{j'}^c Y_j^{q^{\ell}} X_j^{q^{\ell} d}.$$

Finally, we define $\mathbf{Z}^{a,b,c,d,\ell} = \left(\mathbf{Z}_{j,j'}^{a,b,c,d,\ell}\right)_{(j,j') \in J}$ such that:

$$\mathbf{Z}_{j,j'}^{a,b,c,d,\ell} \stackrel{\text{def}}{=} \mathbf{U}_{j,j'}^{a,b,c,d,\ell} + \overline{\mathbf{U}}_{j,j'}^{a,b,c,d,\ell}.$$

The linear system $\mathcal{L}_{\mathbf{P}}$ rewrites then as:

$$\sum_{k+1 \leqslant j < j' \leqslant n} p_{i,j} p_{i,j'} \mathbf{Z}_{j,j'}^{a,b,c,d,\ell} = 0.$$

By construction, there exists relations occurring between some $\mathbf{Z}^{a,b,c,d,\ell}$'s. For instance we always have $\mathbf{Z}^{a,b,a,b,\ell} = 0$ for any integers a, b and ℓ. We also have other basic relations:

Lemma 7: Let integers a, b, c, d, e, f be in $\{0, \ldots, r-1\}$, and an integer ℓ be in $\{0, \ldots, m-1\}$ such that $a + q^{\ell} b = c + q^{\ell} d$. We have:

$$\mathbf{Z}^{a,b,c,d,\ell} + \mathbf{Z}^{c,d,e,f,\ell} = \mathbf{Z}^{a,b,e,f,\ell}. \tag{14}$$

Without loss of generality, we can assume that $d > b$ and let us set $\delta = d - b$. Moreover, as we have $a + q^{\ell} b = c + q^{\ell} d$, it implies that $a = c + q^{\ell} \delta$. Thus, any vector $\mathbf{Z}^{a,b,c,d,\ell}$ is uniquely described by the tuple (b, c, δ, ℓ) by setting $d = b + \delta$ and $a = c + q^{\ell} \delta$ provided that $1 \leqslant \delta \leqslant r - 1 - b$ and $0 \leqslant c + q^{\ell} \delta \leqslant r - 1$.

The next proposition shows that some vectors $\mathbf{Z}^{c+q^{\ell}\delta,b,c,b+\delta,\ell}$ can be expressed as a linear combination of vectors defined with $\delta = 1$.

Proposition 2: Let ℓ, δ, b and c be integers such that $\ell \geqslant 0, \delta \geqslant 1, 1 \leqslant b + \delta \leqslant r - 1$ and $1 \leqslant c + q^{\ell} \delta \leqslant r - 1$. For all $1 \leqslant i \leqslant \delta$, we set $b_i \stackrel{\text{def}}{=} b + i - 1$ and $c_i \stackrel{\text{def}}{=} c + q^{\ell}(\delta - i)$. We have

$$\mathbf{Z}^{c+q^{\ell}\delta,b,c,b+\delta,\ell} = \sum_{i=1}^{\delta} \mathbf{Z}^{c_i+q^{\ell},b_i,c_i,b_i+1,\ell}. \tag{15}$$

Proof: When $\delta = 1$, the equality (15) is obviously verified. We now assume that $\delta \geqslant 2$. Let $b^* \stackrel{\text{def}}{=} b + 1$, $\delta^* \stackrel{\text{def}}{=} \delta - 1$ and $c^* \stackrel{\text{def}}{=} c + q^{\ell}\delta^*$. Then c^* is the integer such that $c^* + q^{\ell} = c + q^{\ell}\delta$, one can see that $c + q^{\ell}\delta^* = c + q^{\ell}(\delta - 1) = c^*$. By Lemma 7 we have:

$$\begin{aligned} \mathbf{Z}^{c^*+q^{\ell},b,c^*,b+1,\ell} + \mathbf{Z}^{c+q^{\ell}\delta^*,b^*,c,b^*+\delta^*,\ell} &= \mathbf{Z}^{c^*+q^{\ell},b,c,b^*+\delta^*,\ell} \\ &= \mathbf{Z}^{c+q^{\ell}\delta,b,c,b+\delta,\ell}. \end{aligned}$$

This means that

$$\mathbf{Z}^{c+q^{\ell}\delta,b,c,b+\delta,\ell} = \mathbf{Z}^{c^*+q^{\ell},b,c^*,b+1,\ell} + \mathbf{Z}^{c+q^{\ell}\delta^*,b^*,c,b^*+\delta^*,\ell}.$$

The proof follows by induction. ∎

Remark 1: Note that if we have t $0 \leqslant a, b, c, d < r, 0 \leqslant \ell < m$ be such that $a + q^{\ell} b = c + q^{\ell} d$ then we also have $0 \leqslant \ell \leqslant \lfloor \log_q(r-1) \rfloor$.

From Proposition 2, we can deduce that the set of vectors $\mathbf{Z}^{c+q^\ell\delta,b,c,b+\delta,\ell}$ obtained with tuples (δ,b,c,ℓ) such that $\delta=1$ form a spanning set. Actually, we can characterize more precisely this set.

Definition 9: Let $\mathcal{B}_r$ be the set of *nonzero* vectors $\left\{\mathbf{Z}^{c+q^\ell,b,c,b+1,\ell} \mid b,c,\ell\right\}$. We then have:

$$\mathcal{B}_r = \left\{\mathbf{Z}^{c+1,b,c,b+1,0} \mid 0 \leqslant b < c \leqslant r-2\right\} \bigcup \left\{\mathbf{Z}^{c+q^\ell,b,c,b+1,\ell} \mid \ 0 \leqslant b \leqslant r-2, 1 \leqslant \ell \leqslant \lfloor \log_q(r-1)\rfloor, 0 \leqslant c \leqslant r-1-q^\ell\right\}$$

We are now in position to conclude for the alternant case.

Proposition 3: Let r be an integer such that $r \geqslant 3$ and let us denote by $|\mathcal{B}_r|$ the cardinality of $\mathcal{B}_r$. Then:

$$T_{\text{alternant}} = m|\mathcal{B}_r|.$$

Proof: Let us set $e \stackrel{\text{def}}{=} \lfloor \log_q(r-1)\rfloor$. Then the number of elements in $\mathcal{B}_r$ is given by the number of tuples (b,c,ℓ). Therefore we get:

$$\begin{aligned}
|\mathcal{B}_r| &= \frac{1}{2}(r-1)(r-2) + \sum_{\ell=1}^{e}\sum_{b=0}^{r-2}(r-q^\ell) \\
&= \frac{1}{2}(r-1)\left(r-2+2er-2\sum_{\ell=1}^{e}q^\ell\right) \\
&= \frac{1}{2}(r-1)\left((2e+1)r-2\sum_{\ell=0}^{e}q^\ell\right) \\
&= \frac{1}{m}T_{\text{alternant}}.
\end{aligned}$$

■

Proposition 3 gives an explanation of the value of $D_{\text{alternant}}$. Indeed, it shows that $\mathcal{B}_r$ is a $\mathbb{F}_{q^m}$-basis that provides a $\mathbb{F}_q$-basis of $\texttt{Ker}(\mathcal{L}_{\mathbf{P}})$ by the following heuristic.

Heuristic 1: Consider a certain decomposition of the elements of $\mathbb{F}_{q^m}$ in a $\mathbb{F}_q$ basis. Let $\pi_i : \mathbb{F}_{q^m} \to \mathbb{F}_q$ be the function giving the i-th coordinate in this decomposition with $1 \leqslant i \leqslant m$. By extension we denote for $\mathbf{z} = (z_j)_{1\leqslant j\leqslant n} \in (\mathbb{F}_{q^m})^n$ by $\pi_i(\mathbf{z})$ the vector $(\pi_i(z_j))_{1\leqslant j\leqslant n} \in \mathbb{F}_q^n$. Then, for any j such that $1 \leqslant j \leqslant n$ and for random choices of x_j's and y_j's, the set $\left\{\pi_i(\mathbf{Z}) \mid 1 \leqslant i \leqslant m \text{ and } \mathbf{Z} \in \mathcal{B}_r\right\}$ forms a basis of $\texttt{Ker}(\mathcal{L}_{\mathbf{P}})$.

In the next section, we will investigate binary Goppa codes. Note that for q-ary Goppa codes of degree $r < q-1$ we observed that $T_{\text{alternant}} = T_{\text{Goppa}}$. In this case, it is easy to see that (5) simplifies to:

$$\frac{1}{2}m(r-1)(r-2) \stackrel{\text{def}}{=} T_{\text{Goppa}}.$$

This is due to the fact that $e=0$ when $r < q-1$. We leave as an open question the proof that q-ary Goppa codes of degree $r < q-1$ behave for our distinguisher as alternant codes. We focus now on the classical case – in code-based cryptography – of binary Goppa codes.

VIII. Binary Goppa Case

The goal of this section is to identify a basis of $\texttt{Ker}(\mathcal{L}_{\mathbf{P}})$ for binary Goppa codes of degree r. We assume therefore that $q=2$. In that special case, the theoretical expression T_{Goppa} (Experimental Fact 2) has a simpler expression.

Proposition 4: Let $e = \lceil \log_2 r\rceil + 1$. When $q=2$, Equation (6) can be simplified to

$$T_{\text{Goppa}} = \frac{1}{2}mr\Big((2e+1)r - 2^e - 1\Big).$$

Theorem 1 shows that a binary Goppa code of degree r can be regarded as a binary alternant code of degree $2r$. This seems to indicate that we should have

$$D_{\text{Goppa}}(r) = T_{\text{alternant}}(2r).$$

This is not the case though. It turns out that $D_{\text{Goppa}}(r)$ is significantly smaller than this. In our experiments, we have found out that the vectors of $\mathcal{B}_{2r}$ still form a generating set for $\texttt{Ker}(\mathcal{L}_{\mathbf{P}})$. Unfortunately, they are not independent anymore. Our goal is therefore to identify the additional dependencies occuring in $\mathcal{B}_{2r}$. We will see that many of them come from $\mathbb{F}_{2^m}$-relations induced by the Goppa polynomial $\Gamma(z)$. Recall that by definition $Y_i = \Gamma(X_i)^{-2}$. This fact will allow to derive two types of linear dependencies. The first type of linear relations is rather natural, whilst the second type is more subtle.

A. Goppa Polynomials: First Linear Dependencies

We will derive the first linear dependencies by means of the Goppa polynomial $\Gamma(X)$.

Proposition 5: Let t, ℓ and c be integers such that $0 \leqslant t \leqslant r-2$, $1 \leqslant \ell \leqslant \lfloor \log_2(2r-1) \rfloor$ and $0 \leqslant c \leqslant 2r - 2^\ell - 1$. We also set $c^* \stackrel{\text{def}}{=} c + 2^{\ell-1}$. It holds that :

$$\sum_{b=0}^{r} \gamma_b^{2^\ell} \mathbf{Z}^{c+2^\ell,t+b,c,t+b+1,\ell} = \mathbf{Z}^{c^*+2^{\ell-1},2t,c^*,2t+1,\ell-1} + \mathbf{Z}^{c+2^{\ell-1},2t+1,c,2t+2,\ell-1}. \tag{16}$$

Proof: Let ℓ, δ, b and c be integers such that $\ell \geqslant 0, \delta \geqslant 1, 1 \leqslant b+\delta \leqslant r-1, 1 \leqslant c + 2^\ell\delta \leqslant r-1$. Let also $d = b+\delta$ and $a = c + 2^\ell\delta$. We can write that for any (j, j') in J (notation being as in (11)):

$$\begin{aligned}
\mathbf{U}_{j,j'}^{a,b,c,d,\ell} &= \mathbf{U}_{j,j'}^{c+2^\ell\delta,b,c,b+\delta,\ell} = Y_j Y_{j'}^{2^\ell} \left(X_j^a X_{j'}^{2^\ell b} + X_j^c X_{j'}^{2^\ell d} \right) \\
&= Y_j Y_{j'}^{2^\ell} X_{j'}^{2^\ell b} \left(X_j^a + X_j^c X_{j'}^{2^\ell \delta} \right) = Y_j Y_{j'}^{2^\ell} X_{j'}^{2^\ell b} X_j^c \left(X_j^{2^\ell\delta} + X_{j'}^{2^\ell\delta} \right) \\
&= \left(X_j^\delta + X_{j'}^\delta \right)^{2^\ell} Y_j X_j^c \left(Y_{j'} X_{j'}^b \right)^{2^\ell}.
\end{aligned}$$

In the same way, we can prove that for all (j, j') in J:

$$\overline{\mathbf{U}}_{j,j'}^{c+2^\ell\delta,b,c,b+\delta,\ell} = \left(X_j^\delta + X_{j'}^\delta \right)^{2^\ell} Y_{j'} X_{j'}^c \left(Y_j X_j^b \right)^{2^\ell}.$$

Observe now that:

$$Y_j X_j^c \left(Y_{j'} X_{j'}^{t+b} \right)^{2^\ell} = Y_j X_j^c Y_{j'}^{2^{\ell-1}} X_{j'}^{2^\ell t} \left(Y_{j'} X_{j'}^{2b} \right)^{2^{\ell-1}}.$$

Let γ_b be the coefficient of z^b in $\Gamma(z)$, that is $\Gamma(z) = \sum_{b=0}^r \gamma_b z^b$. Since $Y_{j'}\Gamma(X_{j'})^2 = 1$, we have $Y_{j'} \sum_{b=0}^{r} \gamma_b^2 X_{j'}^{2b} = 1$. This implies that $\sum_{b=0}^{r} \gamma_b^2 Y_{j'}^2 X_{j'}^{2(b+t)} = Y_{j'} X_{j'}^{2t}$ and then:

$$\sum_{b=0}^{r} \gamma_b^{2^\ell} Y_j X_j^c \left(Y_{j'} X_{j'}^{t+b} \right)^{2^\ell} = Y_j X_j^c \left(Y_{j'} X_{j'}^{2t} \right)^{2^{\ell-1}}.$$

Therefore, we get:

$$\sum_{b=0}^{r} \gamma_b^{2^\ell} \mathbf{U}^{c+2^\ell\delta,t+b,c,t+b+\delta,\ell} = \mathbf{U}^{c'+2^{\ell'}\delta',b',c',b'+\delta',\ell'} \tag{17}$$

with $\ell' = \ell - 1$, $\delta' = 2\delta$, $b' = 2t$, and $c' = c$. Since $c' + 2^{\ell'}\delta' = c + 2^\ell\delta$ and $c + 2^\ell\delta \leqslant 2r-1$ we have $c' + 2^{\ell'}\delta' \leqslant 2r-1$. Moreover, we require $b' + \delta' \leqslant 2r-1$ which means $2(t+\delta) \leqslant 2r-1$. This last inequality implies $t + \delta \leqslant r-1$.

Similarly, we can prove:

$$\sum_{b=0}^{r} \gamma_b^{2^\ell} \overline{\mathbf{U}}^{c+2^\ell\delta,t+b,c,t+b+\delta,\ell} = \overline{\mathbf{U}}^{c'+2^{\ell'}\delta',b',c',b'+\delta',\ell'}.$$

We are now in position to conclude the proof. Thanks to the previous results:

$$\sum_{b=0}^{r} \gamma_b^{2^\ell} \mathbf{Z}^{c+2^\ell,t+b,c,t+b+1,\ell} = \mathbf{Z}^{c+2^\ell,2t,c,2(t+1),\ell-1}$$

Moreover by Proposition 2, we also have:

$$\mathbf{Z}^{c+2^\ell,2t,c,2(t+1),\ell-1} = \mathbf{Z}^{c^*+2^{\ell-1},2t,c^*,2t+1,\ell-1} + \mathbf{Z}^{c+2^{\ell-1},2t+1,c,2t+2,\ell-1}$$

where by definition c^* is equal to $c + 2^{\ell-1}$. ∎

As a consequence, $\mathcal{B}_{2r}$ can not be a basis of $\texttt{Ker}(\mathcal{L}_{\mathbf{P}})$. We count the number of linear dependencies predicted by Proposition 5.

Proposition 6: Let N_L be the number of equations of the form (16) and let us set $u \stackrel{\text{def}}{=} \lfloor \log_2(2r-1) \rfloor$. Then, the following equality holds:

$$N_L = 2(r-1)\left(ru + 1 - 2^u\right).$$

Proof: Each equation is defined by a triple (t, c, ℓ). As $0 \leqslant t \leqslant r-2, 1 \leqslant \ell \leqslant u$ and $0 \leqslant c \leqslant 2r - 2^\ell - 1$. Thus:

$$N_L = \sum_{t=0}^{r-2} \sum_{\ell=1}^{u} (2r - 2^\ell).$$

∎

B. Goppa Polynomials: Additional Linear Dependencies

It turns out that there are still other dependencies. To see this, we define the vector $\mathbf{Q}^{a,b,c,d,\ell} \stackrel{\text{def}}{=} \left(\left(\mathbf{Z}_{j,j'}^{a,b,c,d,\ell} \right)^2 \right)_{(j,j') \in J}$. It immediately follows that:

$$\mathbf{Q}_{j,j'}^{a,b,c,d,\ell} = \left(\mathbf{U}_{j,j'}^{a,b,c,d,\ell} \right)^2 + \left(\overline{\mathbf{U}}_{j,j'}^{a,b,c,d,\ell} \right)^2.$$

We exhibit new linear dependencies between some elements of $\mathcal{B}_{2r}$ and the vectors $\mathbf{Q}_{j,j'}^{a,b,c,d,\ell}$.

Proposition 7: For any integers $b \geqslant 0, t \geqslant 0, \delta \geqslant 1$ and ℓ such that $0 \leqslant \ell \leqslant \lfloor \log_2(2r-1) \rfloor - 1, b + \delta \leq 2r-1$ and $t + 2^\ell \delta \leqslant r-1$, we have

$$\mathbf{Z}^{2t+2^{\ell+1}\delta,b,2t,b+\delta,\ell+1} = \sum_{c=0}^{r} \gamma_c^2 \mathbf{Q}^{c+2^\ell \delta,b,t+c,b+\delta,\ell}. \tag{18}$$

Proof: We recall that $Y_j \Gamma(X_j)^2 = 1$ implies that $\sum_{c=0}^{r} \gamma_b^2 Y_j^2 X_j^{2(c+t)} = Y_j X_j^{2t}$. Thus, for any (j, j') in J, we have:

$$\begin{aligned} W &\stackrel{\text{def}}{=} \sum_{c=0}^{r} \gamma_c^2 \left(\mathbf{U}_{j,j'}^{c+2^\ell \delta,b,t+c,b+\delta,\ell} \right)^2 \\ &= \left(X_j^\delta + X_{j'}^\delta \right)^{2^{\ell+1}} \left(Y_{j'} X_{j'}^b \right)^{2^{\ell+1}} X_j^{2t} Y_j^2 \sum_{c=0}^{r} \gamma_c^2 X_j^{2c} = \left(X_j^\delta + X_{j'}^\delta \right)^{2^{\ell+1}} \left(Y_{j'} X_{j'}^b \right)^{2^{\ell+1}} Y_j X_j^{2t} \\ &= \mathbf{U}_{j,j'}^{c'+2^{\ell'}\delta,b',c',b'+\delta',\ell'} \end{aligned}$$

with $\ell' = \ell + 1$, $\delta' = \delta$, $b' = b$, $c' = 2t$ and $c' + 2^{\ell'}\delta' = 2t + 2^{\ell+1}\delta$. In particular, one can easily check that the necessary conditions are $b + \delta \leq 2r-1$ and $t + 2^\ell \delta \leqslant r-1$ in order for this equation to hold. We finish the proof by doing the same procedure for

$$\sum_{c=0}^{r} \gamma_c^2 \left(\overline{\mathbf{U}}_{j,j'}^{c+2^\ell \delta,b,t+c,b+\delta,\ell} \right)^2 = \overline{\mathbf{U}}_{j,j'}^{c'+2^{\ell'}\delta,b',c',b'+\delta',\ell'}.$$

■

We can count the number of linearly dependencies predicted by Proposition 7.

Proposition 8: Let N_Q he number of vectors of $\mathcal{B}_{2r}$ satisfying Equation (18) and let us set $u \stackrel{\text{def}}{=} \lfloor \log_2(2r-1) \rfloor$. Then we have that

$$N_Q = (2r-1)(ru - 2^u + 1).$$

Proof: By Proposition 7 we know that N_Q is the number of vectors $\mathbf{Z}^{2t+2^{\ell+1}\delta,b,2t,b+\delta,\ell+1}$ obtained with $\delta = 1$, $b \geqslant 0$, $t \geqslant 0$ and satisfying $0 \leqslant \ell \leqslant u-1$, $b + \delta \leq 2r-1$ and $t + 2^\ell \delta \leqslant r-1$. Therefore:

$$N_Q = \sum_{l=0}^{u-1} \sum_{t=0}^{r-1-2^\ell} (2r-1). \tag{19}$$

■

We now want to count the number of linear dependencies induced by Proposition 7 and Proposition 5. The difficulty is that some of the N_Q vectors of $\mathcal{B}_{2r}$ are counted twice because they appear both in linear relations of the form (16) and "quadratic" equations of the form (18). Let $N_{L \cap Q}$ be the number of such vectors. More precisely, let $\mathcal{B}_{2r}^{\text{quad}}$ be the subset of vectors of $\mathcal{B}_{2r}$ which are involved in an Equation of type (18). There are equations of type (16) which involve only vectors of $\mathcal{B}_{2r}^{\text{quad}}$. Let N_1 be their numbers. Moreover, it is possible by adding two equations of type (16) involving at least one vector which is not in $\mathcal{B}_{2r}^{\text{quad}}$ to obtain an equation which involves only vectors of $\mathcal{B}_{2r}^{\text{quad}}$. Let N_0 be the number of such sums. Finally, let $N_{L \cap Q} \stackrel{\text{def}}{=} N_1 + N_0$. It is possible to count such equations.

Proposition 9: $N_{L \cap Q} = (r-1)\Big((u - \frac{1}{2})r - 2^u + 2 \Big)$ where $u \stackrel{\text{def}}{=} \lfloor \log_2(2r-1) \rfloor$.

Proof: We will consider vectors $\mathbf{Z}^{c+2^\ell,b,c,b+1,\ell}$ of $\mathcal{B}_{2r}$ that satisfy Equation (18) and such that there exists a linear relation that link them. In other words, we consider all the linear relations of the form

$$\sum_i \alpha_i \mathbf{Z}^{c_i+2^{\ell_i},b_i,c_i,b_i+1,\ell_i} = 0$$

with α_i in $\mathbb{F}_{2^m}$ and where each $\mathbf{Z}^{c_i+2^{\ell_i},b_i,c_i,b_i+1,\ell_i}$ is equal to a linear relation of the form (18). We will see that the number of *independent* equations is equal to $N_{L \cap Q}$. First, one can observe that for any such vectors we necessary have c_i even and

$1 \leqslant \ell_i \leqslant u$. We also know by Proposition 5 that for any integers t, ℓ and c such that $0 \leqslant t \leqslant r-2$, $1 \leqslant \ell \leqslant u$ and $0 \leqslant c \leqslant 2r - 2^\ell - 1$, we have the following linear relation:

$$\sum_{b=0}^{r} \gamma_b^{2^\ell} \mathbf{Z}^{c+2^\ell,t+b,c,t+b+1,\ell} = \mathbf{Z}^{c^*+2^{\ell-1},2t,c^*,2t+1,\ell-1} + \mathbf{Z}^{c+2^{\ell-1},2t+1,c,2t+2,\ell-1}$$

where by definition $c^* = c + 2^{\ell-1}$. Note in particular that whenever c is even then c^* is also even and if $\ell \geqslant 2$ then we obtain a linear relation between some vectors that also satisfy quadratic equations of the form (18). Each equation enables to remove one quadratic equation. So if we denote by N_1 the number of equations of the form of (16) with c even and $\ell \geqslant 2$, we then have:

$$\begin{aligned} N_1 &= \sum_{t=0}^{r-2} \sum_{\ell=2}^{u} \left(\frac{1}{2}(2r - 2^\ell) \right) \\ &= (r-1) \sum_{\ell=1}^{u-1} (r - 2^\ell) \\ &= (r-1)\Big((u-1)r - 2^u + 2\Big). \end{aligned} \tag{20}$$

Moreover in the case $\ell = 1$, Equation (17) becomes

$$\sum_{b=0}^{r} \gamma_b^2 \mathbf{Z}^{c+2,t+b,c,t+b+1,1} = \mathbf{Z}^{c+2,2t,c,2t+2,0}.$$

In particular, when c is even, say for instance $c = 2t'$ for some integer, then this last equation can be rewritten as:

$$\sum_{b=0}^{r} \gamma_b^2 \mathbf{Z}^{2t'+2,t+b,2t',t+b+1,1} = \mathbf{Z}^{2t'+2,2t,2t',2t+2,0}. \tag{21}$$

We know that when $t' = t$ then $\mathbf{Z}^{2t'+2,2t,2t',2t+2,0}$ is zero. In that case we obtain new relations between vectors satisfying quadratic equations that are independent even from those obtained with $\ell \geqslant 2$. As for the case when $t \neq t'$ we also have

$$\mathbf{Z}^{2t'+2,2t,2t',2t+2,0} = \mathbf{Z}^{2t+2,2t',2t,2t'+2,0}.$$

From this identity and from Equation (21) we then obtain new relations of the following form:

$$\sum_{b=0}^{r} \gamma_b^2 \mathbf{Z}^{2t'+2,t+b,2t',t+b+1,1} = \sum_{b=0}^{r} \gamma_b^2 \mathbf{Z}^{2t+2,t'+b,2t,t'+b+1,1}. \tag{22}$$

This last equation involves only vectors that satisfy also quadratic equations. So the number N_0 of equations of the form (22) is given by the number of sets $\{t, t'\}$. But by assumption t and t' should satisfy $0 \leqslant t \leqslant r-2$ and $c = 2t'$ with $0 \leqslant c \leqslant 2r-3$, which implies that $0 \leqslant t' \leqslant r-2$. Therefore, N_0 is equal to the number (t, t') such that $t \leqslant t'$ and thus we get:

$$N_0 = \sum_{t=0}^{r-2} \sum_{t'=t}^{r-2} = \frac{1}{2}(r-1)r. \tag{23}$$

Finally, by gathering all the cases we therefore obtain that:

$$N_{L \cap Q} = N_1 + N_0 = (r-1)\Big((u-1)r - 2^u + 2\Big) + \frac{1}{2}(r-1)r.$$

■

Proposition 10: For any integer $r \geqslant 2$, we have

$$\frac{1}{m} T_{\text{Goppa}}(r) = |\mathcal{B}_{2r}| - N_L - N_Q + N_{L \cap Q}.$$

Proof: Set $u \stackrel{\text{def}}{=} \lfloor \log_2(2r-1) \rfloor$. From Equation (5), we have

$$|\mathcal{B}_{2r}| = (2r-1)\left((2u+1)r - 2^{u+1} + 1\right)$$

which implies from Proposition 8

$$\begin{aligned} |\mathcal{B}_{2r}| - N_Q &= (2r-1)\left((2u+1)r - 2^{u+1} + 1\right) \\ &- (2r-1)\left((ru - 2^u + 1)\right) \\ &= (2r-1)((u+1)r - 2^u). \end{aligned}$$

TABLE I
A BINARY GOPPA CODE OF LENGTH $n = 2^m$ AND DEGREE $r < r_{\max}$ IS DISTINGUISHABLE FROM A RANDOM CODE.

m	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23
$r_{\max}$	5	8	8	11	16	20	26	34	47	62	85	114	157	213	290	400
$\lceil r_{\text{crit}} \rceil$	5	6	8	11	14	19	25	34	46	62	84	114	156	214	293	402

Moreover, from Proposition 6 and Proposition 9, we can write:

$$\begin{aligned} N_L - N_{L\cap Q} &= (r-1)(2ur + 2 - 2^{u+1}) \\ &- (r-1)(ur - \frac{r}{2} - 2^u + 2) \\ &= (r-1)\Big((u+\frac{1}{2})r - 2^u\Big). \end{aligned}$$

Therefore by gathering all these equalities we obtain:

$$|\mathcal{B}_{2r}| - (N_L + N_Q - N_{L\cap Q}) = r\left((u+\frac{3}{2})r - 2^u - \frac{1}{2}\right).$$

On the other hand from Proposition 4, we have

$$\frac{1}{m}T_{\text{Goppa}}(r) = \frac{1}{2}r\left((2e+1)r - 2^e - 1\right)$$

where $e = \lceil \log_2 r \rceil + 1$. Using the basic inequality $2r - 1 < 2r < 2(2r-1)$, we have therefore

$$\log_2(2r-1) < \log_2(r) + 1 < \log_2(2r-1) + 1$$

which finally implies $\lceil \log_2 r \rceil = u$. Thus, $\frac{1}{m}T_{\text{Goppa}}(r) = \frac{1}{2}r\left((2u+3)r - 2^{u+1} - 1\right)$. ■

IX. CONCLUSION AND CRYPTOGRAPHIC IMPLICATIONS

Based upon these experimental observations, it is straightforward to define a *distinguisher* between random codes, alternant codes and Goppa codes.

Definition 10: Let m and r be integers such that $m \geqslant 1$ and $r \geqslant 1$. Let $\mathbf{G}$ be a $k \times n$ matrix whose entries are in $\mathbb{F}_q$ with $n \leqslant q^m$ and $k \stackrel{\text{def}}{=} n - rm$. Without loss of generality, we assume that $\mathbf{G}$ is systematic *i.e.*, $\mathbf{G} = (\mathbf{I}_k \mid \mathbf{P})$. Let $\mathcal{L}_{\mathbf{P}}$ be the linear system associated to $\mathbf{G}$ as defined in (4), and D be the dimension of $\texttt{Ker}(\mathcal{L}_{\mathbf{P}})$. We define the *Random Code Distinguisher* $\mathcal{D}$ as the mapping which takes as input $\mathbf{G}$ and outputs $\mathcal{D}(G)$ in $\{-1, 0, 1\}$ such that:

$$\mathcal{D}(G) = \begin{cases} -1 & \text{if } D = T_{\text{alternant}} \\ 0 & \text{if } D = T_{\text{Goppa}} \\ 1 & \text{otherwise.} \end{cases} \tag{24}$$

The existence of a distinguisher for the specific case of binary Goppa codes is not valid for any value of r and m but tends to be true for codes that have a rate $\frac{n-mr}{n}$ very close to one. We will elaborate on this point below. This kind of codes are mainly encountered with the signature scheme [1]. If we assume that the length n is equal to 2^m and we denote by $r_{\max}$ the smallest integer r such that $N - T_{\text{Goppa}} \geqslant 2^m - mr$ then any binary Goppa code of degree $r < r_{\max}$ can be distinguished (Table I). For example, the binary Goppa code obtained with $m = 13$ and $r = 19$ corresponding to a 90-bit security McEliece public key is distinguishable. More interestingly, all the keys proposed in [17] for the CFS signature scheme can be distinguished.

Asymptotic Behaviour. When the length n of the code goes to infinity an asymptotic formula can be derived for the smallest rate R_{crit} allowing distinguish a random code from an alternant code or a Goppa code. We derive such a formula when we assume for simplicity that the cardinality q of the base field is fixed and n is chosen as $n = q^m$ (in practice n is chosen either in this way or at least of the same order as q^m). We also assume that the dimension k of the code satisfies $k = n - rm$. We denote the rate k/n of the code by R. Finally, we also make the assumption that the dimensions $D_{\text{alternant}}$ and D_{Goppa} are given by their theoretical values $T_{\text{alternant}}$ and T_{Goppa} respectively and that the dimension of D_{random} is given by $T_{\text{random}} \stackrel{\text{def}}{=} \max\left(0, \binom{mr}{2} - k\right)$. This critical rate r_{crit} corresponds to the smallest value of r for which T_{random} becomes bigger than $T_{\text{alternant}}$ (asymptotically there will be no difference between Goppa codes or alternant codes). It holds that:

$$r_{\text{crit}} \stackrel{\text{def}}{=} \min\{r > 0 : T_{\text{random}} \geq T_{\text{alternant}}\}.$$

We let $R_{\text{crit}} \stackrel{\text{def}}{=} \dfrac{n - r_{\text{crit}}m}{n} = 1 - \dfrac{r_{\text{crit}}m}{n}$. Our claim is that

Theorem 3: Let $n = q^m$. When q is fixed and m tends to infinity, we have

$$r_{\text{crit}} = \sqrt{\frac{2\,q^m \log q}{m \log m}}\big(1 + o(1)\big),$$

$$R_{\text{crit}} = 1 - \sqrt{\frac{2\,m\,\log q}{q^m \log m}}\big(1 + o(1)\big).$$

where all logarithms are taken to base 2.
The proof of this theorem is given in the appendix.

In Table I, we have computed the value of $\left\lceil \sqrt{\frac{2q^m \log q}{m \log m}} \right\rceil$ for several m (q is equal to 2). This shows that our approximation is rather close to $r_{\max}$ computed in practice (even for small values of m).

Concluding remarks. We emphasize that the existence of such a distinguisher does not undermine the security of [2] and [1]. It only shows that the GD assumption should be used in any security reduction with great care.

It has also been observed in [38] that our distinguisher is equivalent to consider the dimension of the square code of the dual of the public code. It should be added that this notion has been used recently to cryptanalyze sucessfully two cryptographic schemes both of them relying on modified generalized Reed-Solomon codes [39], [40].

Finally, we mention that [41] shows that the natural reduction of GD to a hidden subgroup problem yields negligible information. As a consequence, they rule out the direct analogue of a quantum attack using the so-called Quantum Fourier Sampling (QFS) which breaks number theoretic problems [42]. More precisely, [41] shows that QFS has a negligible advantage against GD when the rate is $\geq 1 - \frac{\log_q(n)^{3/2}}{\sqrt{5n}} = R_{\text{QFS}}$. Whilst our result is somewhat contradictory with [41], it is interesting to observe that R_{crit} and the critical rate R_{QFS} share some similarities.

B. Proof of Theorem 3

To prove Theorem 3 we will first use the following observation

Lemma 8: Let $T_{\text{alternant}}$ be as defined in (5). Let also T_{Goppa} be as defined in (6). There exists constants K_1 and K_2 (resp. K_1' and K_1' and K_2') such that

$$mr^2\big(\log_q(r) + K_1\big) \quad \leq T_{\text{alternant}} \quad \leq mr^2\big(\log_q(r) + K_2\big), \tag{25}$$

$$mr^2(\log_q(r) + K_1') \quad \leq T_{\text{Goppa}} \quad \leq mr^2(\log_q(r) + K_2'). \tag{26}$$

Proof: We recall that

$$T_{\text{alternant}} \stackrel{\text{def}}{=} \frac{1}{2}m(r-1)\left((2e+1)r - 2\frac{q^{e+1}-1}{q-1}\right)$$

where $e \stackrel{\text{def}}{=} \left\lfloor \log_q(r-1) \right\rfloor$. First, we remark that there exists some absolute constants K_3 and K_4 such that for all integers $r \geq 2$

$$2r\log_q(r) + K_3 r \leq (2e+1)r - 2\frac{q^{e+1}-1}{q-1} \leq 2r\log_q(r) + K_4 r. \tag{27}$$

The upper bound is clear since:

$$(2e+1)r - 2\frac{q^{e+1}-1}{q-1} \leq 2r\log_q(r) + 2r.$$

For the lower bound, we remark that:

$$e \geq \log_q(r-1) - 1 = \log_q(r) + \log_q(1-1/r) - 1.$$

In addition:

$$\frac{q^{e+1}-1}{q-1} \leq q \cdot q^e \leq rq.$$

As a consequence:

$$\left((2e+1)r - 2\frac{q^{e+1}-1}{q-1}\right) \quad \geq \quad 2r\log_q(r) + r\big(2\log_q(1-1/r) - 1 - 2q\big).$$

Finally, remark that $\log_q(1-1/r)$ can be bounded from above by some (negative) constant. So, it holds that:

$$\left((2e+1)r - 2\frac{q^{e+1}-1}{q-1}\right) \geq 2r\log_q(r) + K_3 r,$$

for some constant K_3.

Observe now that

$$\frac{1}{2}m(r-1)\left(2\log_q(r)+K_3r\right)=\frac{1}{2}(mr-m)\left(2\log_q(r)+K_3r\right)=\frac{1}{2}\left(2mr\log_q(r)+K_3mr^2-2m\log_q(r)-K_3mr\right).$$

The lower bound on $T_{\text{alternant}}$ follows immediately from this. The expression can be lower bounded (resp. upper bounded) by a term of the form K_1mr^2 (resp. K_2mr^2) for some constant K_1 (resp. K_2). This holds for all positive integers r.

Finally, we recall that

$$T_{\text{Goppa}} \stackrel{\text{def}}{=} \begin{cases} \frac{1}{2}m(r-1)(r-2) = T_{\text{alternant}} \text{ for } r < q-1, \\ \\ \frac{1}{2}mr\Big((2e+1)r-2q^e+2q^{e-1}-1\Big) \text{ for } r \geqslant q-1, \end{cases}$$

with e being the unique integer such that:

$$(q-1)^2q^{e-2} < r \leqslant (q-1)^2q^{e-1}.$$

The bound (26) on can be proved in the same way. ∎

From this lemma, we deduce that

Lemma 9: There exist two constants C_1 and C_2 such that for every r satisfying $\binom{mr}{2} \geq n-mr$ we have

$$mr^2\left(m/2-\log_q(r)+C_1\right)-q^m \leq T_{\text{random}}-T_{\text{alternant}} \quad , \tag{28}$$

$$mr^2\left(m/2-\log_q(r)+C_2\right)-q^m \geq T_{\text{random}}-T_{\text{alternant}} \quad . \tag{29}$$

We also have the same inequalities when we replace $T_{\text{random}}-T_{\text{alternant}}$ with $T_{\text{random}}-T_{\text{Goppa}}$.

Proof: For all positive integer values of r such that $\binom{mr}{2} \geq n-mr$, we have:

$$\begin{aligned} T_{\text{random}} &= N-k, \\ &= \binom{mr}{2}-q^m+mr, \\ &= m^2r^2/2-q^m+mr/2. \end{aligned}$$

We can then conclude using Lemma 8. ∎

From this lemma, we derive the following estimate for r_{crit}:

Lemma 10: When m goes to infinity we have

$$r_{\text{crit}} = \sqrt{\frac{2q^m\log q}{m\log m}}\big(1+o(1)\big).$$

Proof: From Lemma 9, we know that:

$$T_{\text{random}}-T_{\text{alternant}} = mr^2\left(m/2-\log_q(r)\right)-q^m+O(mr^2).$$

Let $r_0 \stackrel{\text{def}}{=} \sqrt{\frac{2q^m\log q}{m\log m}}$. It holds that:

$$\begin{aligned} 2\log_q(r_0) &= \log_q(2q^m\log q)-\log_q(m\log m), \\ &= m+\log_q(2\log q)-\log_q(m)-\log_q(\log m). \end{aligned}$$

Thus:

$$\begin{aligned} mr_0^2\left(m/2-\log_q r_0\right)-q^m &= \frac{2q^m\log q}{\log m}\left(m/2-m/2-\frac{\log(2\log q)}{2\log q}+\frac{\log m}{2\log q}+\frac{\log\log m}{2\log q}\right)-q^m, \\ &= \frac{q^m}{\log m}\left(\log\log m-\log(2\log q)\right). \end{aligned}$$

We also observe that

$$mr_0^2 = \frac{2q^m\log q}{\log m}$$

is negligible compared to $\frac{q^m}{\log m}\left(\log\log m-\log(2\log q)\right)$ when m goes to infinity. This can be used to show that $T_{\text{random}}-T_{\text{alternant}}$ is positive for $r=\lceil r_0\rceil$ when m is large enough. Therefore for m large enough, we have $r_{\text{crit}} \leq \lceil r_0\rceil$.

On the other hand, let α be any positive constant < 1. We set:

$$r_\alpha \stackrel{\text{def}}{=} \sqrt{\frac{2\alpha q^m \log q}{m \log m}}.$$

Notice that the function $f(x) = mx^2\left(m/2 - \log_q x\right) - q^m$ can be shown to be increasing in the range $(0, r_\alpha)$. Therefore for every $r \leq r_\alpha$, we have

$$\begin{aligned} mr^2\left(m/2 - \log_q r\right) - q^m &\leq \frac{2\alpha q^m \log q}{\log m}\left(m/2 - m/2 + \frac{\log m}{2\log q} + \frac{\log\log m}{2\log q} - \frac{\log(2\alpha \log q)}{2\log q}\right) - q^m, \\ &\leq (\alpha - 1)q^m + \frac{2\alpha q^m \log q}{\log m}\left(\frac{\log\log m}{2\log q} - \frac{\log(2\alpha\log q)}{2\log q}\right), \\ &\leq (\alpha-1)q^m + q^m \frac{\alpha \log\log m}{\log m}. \end{aligned}$$

Since $mr^2 \leq \frac{2\alpha q^m \log q}{\log m}$, it follows that any function of the form $mr^2\left(m/2 - \log_q r\right) - q^m + O(mr^2)$ will be negative for m large enough in the range $(0, r_\alpha)$.

This implies that $r_{\text{crit}} \geq r_\alpha = \sqrt{\frac{2\alpha q^m \log q}{m \log m}}$ for m large enough. We deduce from this fact which holds for any $0 < \alpha < 1$ and from the upper bound $r_{\text{crit}} \leq \lceil r_0 \rceil = \left\lceil \sqrt{\frac{2q^m \log q}{m \log m}} \right\rceil$ that $r_{\text{crit}} = \sqrt{\frac{2q^m \log q}{m \log m}}(1 + o(1))$ when m goes to infinity.

Finally, the proof of Theorem 3 is now obtained as follows. We have

$$\begin{aligned} R_{\text{crit}} &= \frac{q^m - mr_{\text{crit}}}{q^m}, \\ &= 1 - \sqrt{\frac{2\,m\,\log q}{q^m \log m}}\big(1 + o(1)\big). \end{aligned}$$
