Abstract

Arora & Ge [5] recently showed that solving LWE can be reduced to solve a high-degree non-linear system of equations. They used a linearization to solve the systems. We investigate here the possibility of using Gröbner bases to improve Arora & Ge approach.

Introduction

The Learning With Errors (LWE) Problem was introduced by Regev in [27, 26]. It is a generalisation for large primes of the well-known LPN (Learning Parity with Noise) problem. Since its introduction, LWE has become a source of many innovative cryptosystems, such as the oblivious transfer protocol by Peikert et al. [25], a cryptosystem by Akavia et al. [1] that is secure even if almost the entire secret key is leaked, homomorphic encryption [21, 10, 4], etc. . . Reasons of LWE's success in cryptography include its simplicity as well as convincing theoretical arguments regarding its hardness, i.e. a reduction from (worst-case) assumed hard lattice problems to (average-case) LWE.

The purpose of this paper is to investigate whether algebraic techniques (e.g. [16, 17, 18, 19, 3, 2, 20]) can be used in the context of LWE. This is motivated by a recent result Arora & Ge [5] who showed that solving LWE can be reduced to solve a high-degree non-linear system of equations.

Learning With Errors

We reproduce below the definition of the LWE problem from [27, 26].

Definition 1 (LWE). *Let $n \geq 1$ be the number of variables, q be an odd prime integer, χ be a probability distribution on \mathbb{Z}_q and \mathbf{s} be a secret vector in \mathbb{Z}_q^n . We denote by $L_{\mathbf{s}, \chi}^{(n)}$ the probability distribution on $\mathbb{Z}_q^n \times \mathbb{Z}_q$ obtained by choosing $\mathbf{a} \in \mathbb{Z}_q^n$ at random, choosing $e \in \mathbb{Z}_q$ according to χ , and returning $(\mathbf{a}, c) = (\mathbf{a}, \langle \mathbf{a}, \mathbf{s} \rangle + e) \in \mathbb{Z}_q^n \times \mathbb{Z}_q$. LWE is the problem of finding $\mathbf{s} \in \mathbb{Z}_q^n$ given pairs $\mathbb{Z}_q^n \times \mathbb{Z}_q$ sampled according to $L_{\mathbf{s}, \chi}^{(n)}$.*

The modulus q is typically taken to be polynomial in n , and χ is the discrete Gaussian distribution on \mathbb{Z}_q with mean 0 and standard deviation $\sigma = \alpha \cdot q$, for some α . To discretize the Gaussian distribution $\mathbb{N}0, \sigma^2$ modulo q , we sample according to $\mathbb{N}0, \sigma^2$ and round to the nearest integer mod q . In what follows, $\chi_{\alpha, q}$ will then denote this discretized distribution.

A typical setting for the standard deviation (std) is $\sigma = n^\epsilon$, with $\epsilon, 0 \leq \epsilon \leq 1$. For example, [27] suggests $q \approx n^2$ and $\alpha = 1/(\sqrt{n} \cdot \log^2 n)$. Indeed, as soon as $\epsilon \geq 1/2$ (worst-case) GAPSVP $-\tilde{O}(n/\alpha)$ reduces to (average-case) LWE¹. Thus, any algorithm solving LWE (when $\epsilon \geq 1/2$) can be used for GAPSVP $-\tilde{O}(n/\alpha)$. We emphasize that it is widely believed that only exponential algorithm exists for solving GAPSVP $-\tilde{O}(n/\alpha)$.

Recently, Arora & Ge [5] introduced a variant of LWE with *structured* errors. In this setting, you have given an oracle such that given LWE samples returns polynomials which vanish on the errors.

¹The reduction is quantum if q is polynomial but can be made [24] classical if q is super polynomial.

They showed that the (discretized) Gaussian intrinsically induced a structure on the errors. This feature can be used to reduce LWE to the problem of solving a non-linear system of multivariate equations.

The total complexity (time and space) of their approach is $2^{\tilde{O}(n^{2\varepsilon})}$. It is then subexponential when $\varepsilon < 1/2$, but remains exponential when $\varepsilon \geq 1/2$. It is interesting that Arora&Ge reach with a completely different approach the $\varepsilon = 1/2$ hardness limit advised by Regev [27, 26].

Note that an improvement on Arora&Ge could allow to challenge the ‘subexponentiality’ of GAPSVP – $\tilde{O}(n/\alpha)$. Remark that [5] uses linearization to solve the non-linear system. It is then natural to investigate whether more advanced tools, such as Gröbner bases [11, 12, 13], could improve the algorithm of Arora&Ge.

In this note, we will show that Gröbner bases can bring a practical improvement on the complexity of [5]. We also briefly discuss whether Gröbner bases can (or can not) allow to change the complexity class of Arora&Ge. Before that, we need to recall some basic complexity results about Gröbner bases.

Gröbner bases – Complexity Results

Gröbner basis is probably the main tool allowing to solve non-linear system of finite fields. From an algorithmic point of view, Lazard [22] showed that computing the Gröbner basis for a system of polynomials is equivalent to perform a Gaussian elimination on the *Macaulay matrices* [23] $\mathcal{M}_{d,m}^{\text{acaulay}}$ for $d, 1 \leq d \leq D$ for some integer D . Moreover, the most efficient known algorithms such as F_5 [15] reduce Gröbner basis computations to a series of Gaussian eliminations on matrices of increasing sizes.

Definition 2 (Macaulay Matrix [23]). *Let $f_1, \dots, f_m \in \mathbb{Z}_q[x_1, \dots, x_n]$. The Macaulay matrix $\mathcal{M}_{d,m}^{\text{acaulay}}(f_1, \dots, f_m)$ of degree d is defined as follows: list “horizontally” all the degree d monomials from smallest to largest sorted by some fixed admissible monomial ordering. The smallest monomial comes last. Multiply each f_i by all monomials $t_{i,j}$ of degree $d - d_i$ where $d_i = \deg(f_i)$. Finally, construct the coefficient matrix for the resulting system:*

$$\mathcal{M}_{d,m}^{\text{acaulay}}(f_1, \dots, f_m) := \begin{matrix} & & & & \text{monomials of degree } \leq d \text{ sorted for } < \\ & (t_{1,1}, f_1) & & & \\ & (t_{1,2}, f_1) & & & \\ & \vdots & & & \\ & (t_{m,1}, f_m) & & & \\ & (t_{m,2}, f_m) & & & \\ & \vdots & & & \end{matrix} \left(\begin{matrix} \\ \\ \\ \\ \\ \\ \end{matrix} \right)$$

Theorem 3 ([22]). *Let $\mathbf{f} = (f_1, \dots, f_m) \in (\mathbb{Z}_q[x_1, \dots, x_n])^m$ and $<$ be a monomial ordering. There exists a positive integer D for which Gaussian elimination on all $\mathcal{M}_{d,m}^{\text{acaulay}} = (f_1, \dots, f_m)$ matrices for $d, 1 \leq d \leq D$ computes a Gröbner basis of $\langle f_1, \dots, f_m \rangle$ w.r.t. to $<$. The degree D will be called degree of regularity of f_1, \dots, f_m .*

Consequently, the complexity of computing a Gröbner basis is bounded by the complexity of performing Gaussian elimination on the Macaulay matrix in some degree D . Roughly, the complexity of computing a Gröbner basis with an algorithm based on the degree of regularity (such as – but not limited too – Buchberger’s algorithm, F_4, F_5 [15, 11, 12, 14]) is:

$$o \left(\binom{n+D}{D}^\omega \right), \quad (1)$$

where $2 \leq \omega < 3$ is the linear algebra constant, and D is the degree of semi-regularity of the system.

In general, computing the degree of regularity of a system is a difficult problem. However, it is known for a specific family of polynomial systems [6, 8, 7, 9].

Definition 4 (Semi-regular Sequence [8]). *Let $m > n$, and $f_1, \dots, f_m \in \mathbb{Z}_q[x_1, \dots, x_n]$ be homogeneous polynomials of degrees d_1, \dots, d_m respectively and I the ideal generated by these polynomials. The system is said to be a semi-regular sequence if the Hilbert series [13] of I w.r.t. the grevlex order is:*

$$H_I(z) = \left[\frac{\prod_{i=1}^m (1 - z^{d_i})}{(1 - z)^n} \right]_+, \quad (2)$$

where $[S]_+$ denotes the series obtained by truncating S before the index of its first non-positive coefficient. Thus, the degree of regularity D involved in Theorem 3 for a semi-regular sequence is:

$$1 + \deg(H_I).$$

Improving Arora-Ge Approach

We briefly detail below the linearization approach of Arora-Ge. We then discuss whether Gröbner bases can be used in this context.

Basic Arora-Ge Algorithm – A Linearization Approach

The idea of [5] is to generate a non-linear noise-free system of equations from LWE samples. This is due to the following well-known feature of a Gaussian noise:

Lemma 5. *Let $C > 0$ be a constant. It holds that:*

$$\Pr[e \stackrel{\$}{\leftarrow} \chi_{\alpha, q} : |e| > C \cdot \sigma] \leq e^{o(-C^2)}.$$

As a consequence, elements sampled from a Gaussian distribution only takes values on a (small) subset $[-C \cdot \sigma, \dots, C \cdot \sigma]$ of \mathbb{Z}_q with high probability. From now on, we set $t = C \cdot \sigma$. We can re-interpret Lemma 5 algebraically by considering the polynomial:

$$P(X) = X \prod_{i=1}^t (X + i)(X - i).$$

Clearly P is of degree $2t + 1 \in o(\sigma)$. Thus, if $e \stackrel{\$}{\leftarrow} \chi_{\alpha, q}$, then $P(e) = 0$ with probability at least $1 - e^{o(-C^2)}$.

For $i \geq 1$, let $(\mathbf{a}_i, \langle \mathbf{a}_i, s \rangle + e_i) = (\mathbf{a}_i, b_i) \in \mathbb{Z}_q^n \times \mathbb{Z}_q$. If $e_i \stackrel{\$}{\leftarrow} \chi_{\alpha, q}$, then

$$P(\mathbf{a}_i, \langle \mathbf{a}_i, s \rangle - b_i) = 0, \quad (3)$$

with probability at least $1 - e^{o(-C^2)}$. As a consequence, each sample $(\mathbf{a}_i, \langle \mathbf{a}_i, s \rangle + e_i) = (\mathbf{a}_i, b_i) \in \mathbb{Z}_q^n \times \mathbb{Z}_q$ allows to generate a non-linear equation of degree $2t + 1$ in the n components of the secret \mathbf{s} .

The idea of Arora & Ge is then to generate sufficiently many equations as in (3) to perform a linearization. However, one has to choose the constant – denoted by C_{AG} – occurring in Lemma 5 sufficiently big so that all errors generated lies with high probability in $[-C_{AG} \cdot \sigma, \dots, C_{AG} \cdot \sigma] \subseteq \mathbb{Z}_q$, i.e. the secret \mathbf{s} is indeed a common solution of the M_{AG} equations constructed as in (3). To this end, we set:

$$p_f = \frac{M_{AG}}{e^{o(C_{AG}^2)}}.$$

This is the probably that the secret $s \in \mathbb{Z}_q^n$ is not solution of the system \mathcal{S}_{AG} generated from M_{AG} equations as in (3), i.e. the probability of failure of Arora-Ge approach. Let also $D_{AG} = 2C_{AG} \cdot \sigma + 1$ be the degree of the equations occurring in \mathcal{S}_{AG} . According to [5], taking $C_{AG} \in \tilde{o}(\sigma)$ allows to make the probability of failure negligible.

To summarize, Arora-Ge approach reduces to linearize at system of M_{AG} equations of degree $D_{AG} = 2C_{AG} \cdot \sigma + 1 \in \tilde{o}(\sigma^2)$. Moreover, correctness of this approach can be proven:

Theorem 6. [5] Let $D_{AG} < q$. The system obtained by linearizing $M_{AG} = O\left(q \cdot \log(q) \binom{n+D_{AG}}{D_{AG}} \sigma\right) = n^{O(D_{AG})} = 2^{\tilde{O}(D_{AG})}$ equations as in (3) has at most one solution with high probability.

The time complexity of the basic Arora-Ge approach is then

$$C_{AG}^{\text{plx}} = n^{O(D_{AG})} = 2^{\tilde{O}(\sigma^2)} = 2^{\tilde{O}(n^{2\varepsilon})}.$$

Note also this algorithm also requires $2^{\tilde{O}(n^{2\varepsilon})}$ LWE samples for performing the linearization.

From Linearization to Gröbner Bases

The question we try to address here is whether the complexity C_{AG}^{plx} can be improved by using Gröbner bases instead of linearization. The rationale is that you can decrease the constant C_{AG} (and so the degree of the equations) to a value smaller than $\tilde{O}(n^{2\varepsilon})$ by considering less equations (whilst keeping the probability p_f of failure similar in both approaches). However, the cost of the solving step increases since one has to compute a Gröbner basis. The question is then to find – if any – a tradeoff allowing to improve upon linearization.

To do so, we will consider a number of equations of the form $\sqrt[\theta]{M_{AG}}$, with $\theta > 1$ ($\theta = 1$ is the basic Arora-Ge). We want to keep the probability of failure similar for the linearization and Gröbner basis approaches. As a consequence, we need to take a constant C_θ such that:

$$p_f = \frac{\sqrt[\theta]{M_{AG}}}{e^{O(C_\theta^\theta)}}.$$

An easy calculation leads to $C_\theta \in \tilde{O}\left(\frac{C_{AG}}{\sqrt{\theta}}\right)$. Thus, decreasing the number of equations from M_{AG} to $\sqrt[\theta]{M_{AG}}$ allows to divide the constant C_{AG} by a factor $\sqrt{\theta}$. The degree of the equations we are doing to consider is then equal to $2\sigma \cdot C_\theta + 1 \in \tilde{O}\left(\frac{\sigma^2}{\sqrt{\theta}}\right)$.

The question is now to find a good candidate for θ . Typically, if θ is too big then you will greatly decrease the number of equations, but the cost of the solving step will become prohibitive and the total complexity will be worse than for a linearization.

We have considered a θ of the form: $\theta = n^{2\beta}$, for some $\beta \geq 0$ (note that we get the basic Arora-Ge by taking $\beta = 0$). In this new setting, we get a constant $C_\beta = n^{\varepsilon-\beta}$. We have then to solve a system having $M_\beta = \sqrt[n^{2\beta}]{M_{AG}} \in 2^{\tilde{O}(n^{2(\varepsilon-\beta)})}$ equations of degree $D_\beta = \tilde{O}(n^{2\varepsilon-\beta})$. We denote such a system by $S_{GB}(\beta)$.

The question is to determine the complexity $C_{GB-AG}^{\text{plx}}(\beta)$ of solving $S_{AG}(\beta)$. This reduces to studying its degree of regularity D_{reg}^β . Given current algorithms, the specific structure of the system does not allow to solve it faster than random systems. As a consequence, we assume that D_{reg}^β is not bigger than the degree of regularity of a semi-regular system of the same size², namely:

$$D_{reg}^\beta \leq 1 + \deg(H_\beta),$$

where:

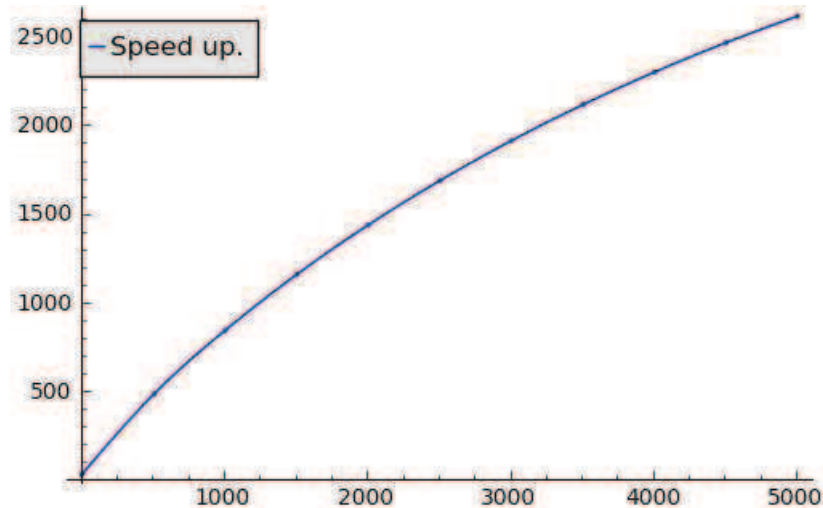

$$H_\beta(z) = \left[\frac{(1-z^{D_\beta})^{M_\beta}}{(1-z)^n} \right]_+,$$

where $[\cdot]_+$ denotes the series obtained by truncating before the index of its first non-positive coefficient.

We present below some experiments performed for $\beta = 1/5$. We have computed explicitly the complexities for both approaches: linearization and Gröbner bases. As suggested in [27],

²We have performed few experiments for small parameters. The experiments seem to confirm this hypothesis.

we considered $q \approx n^2$ and $\alpha = 1/(\sqrt{n} \cdot \log^2 n)$. We plotted below the speed-up we obtained, i.e. $\log_2 \left(\frac{C_{GB-AG}^{plx}(\beta)}{C_{AG}^{plx}} \right)$ (y-axis) for $n, 0 \leq n \leq 5000$. We can see that Gröbner bases allow to improve the complexity of the basic Arora-Ge when $n \leq 5000$ (x-axis). Note that further experiments are required to confirm this behavior when n tends to infinity³

However, the form of the speed-up also tends to suggest that we only improve from a constant C_{AG}^{plx} . change the asymptotical behavior of the Arora&Ge approach. we mention that we are currently considering several forms for the β . In particular, β which is not a constant but a function of n . As a conclusion, we also emphasize that Arora-Ge needs exponential (or subexponential) number of LWE samples. For most cryptosystems based on LWE, you have access to much less samples, typically polynomially-many. In this situation, you have then not enough samples to perform the linearization and the only option to mount the Arora&Ge approach is to solve the system by using Gröbner bases.
