---

Consider a  $(\text{MOD}_q, \text{MOD}_p)$  circuit, where the inputs of the bottom  $\text{MOD}_p$  gates are degree- $d$  polynomials with integer coefficients of the input variables ( $p, q$  are different primes). Using our main tool — the Degree Decreasing Lemma — we show that this circuit can be converted to a  $(\text{MOD}_q, \text{MOD}_p)$  circuit with *linear* polynomials on the input-level with the price of increasing the size of the circuit. This result implies special cases of the Constant Degree Hypothesis of Barrington, Straubing and Thérien [3], and implies also a generalization of the lower bound results of Yan and Parberry [21], Krause and Waack [12] and Krause and Pudlák [11]. Perhaps the most important application is an exponential lower bound for the size of  $(\text{MOD}_q, \text{MOD}_p)$  circuits computing the fan-in  $n$  AND, where the input of each  $\text{MOD}_p$  gate at the bottom is an *arbitrary* integer valued function of  $cn$  variables ( $c < 1$ ) plus an arbitrary linear function of  $n$  input variables.

**Keywords:** Circuit complexity, modular circuits, composite modulus

---

## 1 Introduction

Boolean circuits are one of the most interesting models of computation. They are widely examined in VLSI design, in general computability theory and in complexity theory context as well as in the theory of parallel computation.

Almost all of the strongest and deepest lower bound results for the computational complexity of finite functions were proved using the Boolean circuit model of computation ([13], [22], [9], [14], [15], or see [20] for a survey).

Even these famous and sophisticated lower bound results were proven for very restricted circuit classes.

Bounded depth and polynomial size is one of the most natural restrictions. Ajtai [1], Furst, Saxe, and Sipser [5] proved that no polynomial sized, constant depth circuit can compute the PARITY function. Yao [22] and Håstad [9] generalized this result for sub-logarithmic depths.

---

<sup>†</sup>A preliminary version of this work appeared in the Proceedings of ICALP'98, Springer Verlag, LNCS 1443, pp. 215-222.

Since the modular gates are very simple to define, and they are immune to the random restriction techniques in lower bound proofs for the PARITY function, the following natural question was asked by several researchers: How powerful will become the Boolean circuits if — beside the standard AND, OR and NOT gates —  $\text{MOD}_m$  gates are also allowed in the circuit? Here a  $\text{MOD}_m$  gate outputs 1 iff the sum of its inputs is in a set  $A \subset \{0, 1, 2, \dots, m-1\}$  modulo  $m$ .

Razborov [14] showed that for computing MAJORITY with AND, OR, NOT and  $\text{MOD}_2$  gates, exponential size is needed with constant depth. This result was generalized by Smolensky [15] for  $\text{MOD}_p$  gates instead of  $\text{MOD}_2$  ones, where  $p$  denotes a prime.

Very little is known, however, if both  $\text{MOD}_p$  and  $\text{MOD}_q$  gates are allowed in the circuit for different primes  $p, q$ , or, if the modulus is a non-prime power composite, e.g., 6. For example, it is consistent with our present knowledge that depth-3, linear-size circuits with  $\text{MOD}_6$  gates *only*, recognize the Hamiltonian graphs (see [3]). The existing lower bound results use diverse techniques from Fourier-analysis, communication complexity theory, group-theory and several forms of random restrictions (see [3], [11], [17], [18], [16], [8], [6], [7], [2], [10]).

It is not difficult to see that constant-depth circuits with  $\text{MOD}_p$  gates only ( $p$  prime), cannot compute even simple functions: the fan-in  $n$  OR or AND functions, since they can only compute constant degree polynomials of the input variables over  $\text{GF}_p$  (see [15]).

But depth-2 circuits with  $\text{MOD}_2$  and  $\text{MOD}_3$  gates, or  $\text{MOD}_6$  gates can compute the  $n$ -fan-in OR and AND functions [10], [3]. Consequently, these circuits are more powerful than circuits with  $\text{MOD}_p$  gates only.

By the famous results of Yao [23] and Beigel and Tarui [4], and Toda [19], every polynomial-size, constant-depth circuit with AND, OR, NOT and  $\text{MOD}_m$  gates can be converted to a depth-2 circuit with a SYMMETRIC gate at the top and quasi-polynomially many AND gates of poly-logarithmic fan-in at the bottom. One might hope that this result is an excellent tool for bounding the power of circuits containing modular gates. Unfortunately, the existing lower bound techniques are not strong enough to bound the computational power of these circuits.

Our main contribution here is a lemma, the Degree Decreasing Lemma, which yields a tool for dealing with low-fan-in AND gates at the bottom of  $(\text{MOD}_q, \text{MOD}_p)$  circuits. We believe that — in the light of the result of Yao, Beigel and Tarui — our result may have further important consequences in modular circuit theory.

## 2 Preliminaries

**Definition 1** *A fan-in  $n$  gate is an  $n$ -variable Boolean function. Let  $G_1, G_2, \dots, G_\ell$  be gates of unbounded fan-in. Then a*

$$(G_1, G_2, \dots, G_\ell; d) - \text{circuit}$$

*denotes a depth- $\ell$  circuit with a  $G_1$ -gate on the top,  $G_2$  gates on the second level,  $G_3$  gates on the third level from the top, ..., and  $G_\ell$  gates on the last level. Multi-linear polynomials (i.e., polynomials where the exponent of every variable is 0 or 1) with integer coefficients and of input-variables  $x_1, x_2, \dots, x_n$  of degree at most  $d$  are connected to  $G_\ell$  gates on the last level. The size of a circuit is defined to be the total number of the gates  $G_1, G_2, \dots, G_\ell$  in the circuit.*

All of our gates are of unbounded fan-in, and we allow to connect inputs to gates or gates to gates with multiple wires. Let us remark, that we are interested mainly in circuits with modular gates and with constant moduli; consequently, the number of wires is polynomially related to the number of gates.

In the literature  $\text{MOD}_m$  gates are sometimes defined to be 1, iff the sum of their inputs is divisible by  $m$ , and sometimes they are defined to be 1, iff the sum of their inputs is not divisible by  $m$ . The following, more general definition covers both cases.

**Definition 2** We say that gate  $G$  is a  $\text{MOD}_m$ -gate, if there exists a non-empty  $A \subset \{0, 1, \dots, m-1\}$ , such that

$$G(x_1, x_2, \dots, x_n) = \begin{cases} 1, & \text{if } \sum_{i=1}^n x_i \bmod m \in A \\ 0 & \text{otherwise.} \end{cases}$$

$A$  is called the 1-set of  $G$ .  $\text{MOD}_m$  gates with 1-set  $A$  are denoted by  $\text{MOD}_m^A$ .

**Definition 3** Let  $p$  be a prime. We say that polynomial  $P(x_1, x_2, \dots, x_n)$  over the  $p$  element field is a depth- $d$  polynomial, if it can be computed by an arithmetic circuit from inputs  $x_1, x_2, \dots, x_n$  and constants 1 and 0, as follows: the arithmetic circuit is levelled, the variables and constants 0 and 1 are situated on the lowest level, and multiple wires (i.e., constant multipliers) are allowed in the circuit. The levels of the circuit contains ADDITION and MULTIPLICATION gates, the ADDITION gates are of unbounded fan-in, the MULTIPLICATION gates are of fan-in 2. There are only  $d$  levels where MULTIPLICATION gates occur, and within the same level, one input of each MULTIPLICATION gates are connected to the same node (called the common multiplier on the level), situated one level lower.

In other words, if on the same level there are several MULTIPLICATION gates, and one of them computes  $PQ$ , then all the other MULTIPLICATION gates on the same level should compute  $PR_1, PR_2, \dots, PR_s$  or, alternatively,  $R_1Q, R_2Q, \dots, R_sQ$ , where  $P, Q$  and  $R_i$  for  $i = 1, 2, \dots, s$  denote polynomials, computed in the nodes just below our level.

Note, that we have not bounded the number of gates in the arithmetic circuit, just the number of levels containing multiplications and the structure within the levels.

**Lemma 4** Any multi-linear polynomial with  $n$  variables is a depth- $(n-1)$  polynomial.

**Proof:** We prove by induction. Our induction hypothesis is the following: If  $P(x_1, x_2, \dots, x_n)$  is a multi-linear polynomial of  $n$  variables, then it can be computed by an arithmetic circuit of Definition 3 such that on the first (lowest) multiplication level the common multiplier is  $x_2$ , on the second multiplication level the common multiplier is  $x_3, \dots$ , on the  $n-1$ st multiplication-level the common multiplier is  $x_n$ .

The base case is obvious. The induction step: If  $P(x_1, x_2, \dots, x_n)$  is a multi-linear polynomial, then  $P = x_nQ + R$  where  $Q$  and  $R$  are multi-linear polynomials of variables  $x_1, x_2, \dots, x_{n-1}$ . Consequently, for  $Q$  and  $R$  the induction hypothesis is satisfied with depth  $n-2$ , so we are done.  $\square$

We remark, that linear polynomials are depth-0 polynomials. Polynomial

$$(x_1 + x_2 + x_3 + x_4 + x_5)(x_2 + x_4 + x_5)^2(x_3 + x_5 + 2) + (x_2 + x_4 + x_5)(x_3 + x_1 + x_5) + 12$$

is a depth-2 polynomial.

**Definition 5** Let  $p$  and  $q$  be two different primes, and let  $d$  be a non-negative integer. Then

$$(\text{MOD}_q, \text{MOD}_p; \text{depth} - d)$$

denotes a  $(\text{MOD}_q, \text{MOD}_p)$  circuit, where the input of each  $\text{MOD}_p$ -gate is a depth- $d$  polynomial.

### 3 The Degree-Decreasing Lemma

The following lemma is our main tool. It exploits a surprising property of  $(\text{MOD}_p, \text{MOD}_q)$ -circuits, which lacks in  $(\text{MOD}_p, \text{MOD}_p)$  circuits, since constant-depth circuits with  $\text{MOD}_p$  gates are capable only to compute a constant degree polynomial of the inputs, and this constant depends on the depth, and not on the size.

**Remark 1.** Generally, the inputs of the modular gates are Boolean variables. Here, however, for wider applicability of the lemma, we allow input  $x$  for a general  $\text{MOD}_m$  gate to be chosen from set  $\{0, 1, \dots, m - 1\}$ . This will allow us to substitute polynomials into the variables of the lemma.

**Remark 2.** The output of the general  $\text{MOD}_m$  gates depend only on the sum of the inputs. In the next lemma it will be more convenient to denote  $\text{MOD}_m^A(y_1, y_2, \dots, y_\ell)$  i.e., gate  $\text{MOD}_m^A$  with inputs  $y_1, y_2, \dots, y_\ell$ , by  $\text{MOD}_m^A(y_1 + y_2 + \dots + y_\ell)$ .

**Lemma 6 (Degree Decreasing Lemma)** Let  $p$  and  $q$  be different primes, and let  $x_1, x_2, x_3$  be variables with values from  $\{0, 1, \dots, p - 1\}$ . Then

$$\text{MOD}_q^B(\text{MOD}_p^A(x_1x_2 + x_3)) = \text{MOD}_q^B(H_0 + H_1 + \dots + H_{p-1} + \beta),$$

where  $H_i$  abbreviates

$$H_i = \alpha \sum_{j=0}^{p-1} \text{MOD}_p^A(ix_2 + x_3 + j(x_1 - i))$$

for  $i = 0, 1, \dots, p - 1$ , where  $\alpha$  is the multiplicative inverse of  $p$  modulo  $q$ :  $\alpha p \equiv 1 \pmod{q}$ , and  $\beta$  is a positive integer satisfying  $\beta = -|A|(p - 1)\alpha \pmod{q}$ .

In the special case of  $(\text{MOD}_3, \text{MOD}_2^{\{1\}})$  circuit, the statement of Lemma 6 is illustrated on Figure 1.

**Fig. 1:** Degree-decreasing in the  $(\text{MOD}_3, \text{MOD}_2^{\{1\}})$  case: on the left the input is a degree-2 polynomial, on the right the inputs are linear polynomials.

**Proof:** Let  $x_1 = k$  and let  $0 \leq i \leq p-1$ ,  $k \neq i$ . Then

$$H_k = \alpha \sum_{j=0}^{p-1} \text{MOD}_p^A(kx_2 + x_3) = \alpha p \text{MOD}_p^A(kx_2 + x_3) \equiv \text{MOD}_p^A(x_1x_2 + x_3) \pmod{q},$$

and

$$H_i = \alpha \sum_{j=0}^{p-1} \text{MOD}_p^A(ix_2 + x_3 + j(k-i)) = \alpha|A|,$$

since for any fixed  $x_2, x_3, i, k$  expression  $ix_2 + x_3 + j(k-i)$  takes on every value exactly once modulo  $p$  while  $j = 0, 1, \dots, p-1$ ; so  $\text{MOD}_p^A(ix_2 + x_3 + j(k-i))$  equals to 1 exactly  $|A|$  times. Consequently,

$$\begin{aligned} \text{MOD}_q^B(H_0 + H_1 + \dots + H_{p-1} + \beta) &= \text{MOD}_q^B(\text{MOD}_p^A(x_1x_2 + x_3) + (p-1)\alpha|A| + \beta) \\ &= \text{MOD}_q^B(\text{MOD}_p^A(x_1x_2 + x_3)). \end{aligned}$$

□

## 4 Applications of the Degree Decreasing Lemma

The following theorem facilitates the applications of the Degree Decreasing Lemma:

**Theorem 7** *Suppose, that function  $f: \{0, 1\}^n \rightarrow \{0, 1\}$  can be computed by a  $(\text{MOD}_q^B, \text{MOD}_p^A; \text{depth} - d)$  circuit of size  $s$ , where  $p$  and  $q$  are two different primes, and  $d$  is a non-negative integer. Then  $f$  can also be computed by a  $(\text{MOD}_q^B, \text{MOD}_p^A; 1)$  circuit of size*

$$(p^{2d} + 1)s.$$

**Proof:**

We first show, that our  $(\text{MOD}_q^B, \text{MOD}_p^A; \text{depth} - d)$  circuit of size  $s$  can be converted into a  $(\text{MOD}_q^B, \text{MOD}_p^A; \text{depth} - (d-1))$  circuit of size at most  $p^2s + 1$ . Repeating this conversion  $d-2$  times, the statement follows.

We know that the input of every  $\text{MOD}_p^A$ -gate can be constructed with at most  $d$  multiplications in an arithmetic circuit. Let us consider a fixed  $\text{MOD}_p^A$ -gate. Suppose, that the last multiplication, which computes its input-polynomial is  $PQ + R$ , where  $P, Q, R$  are  $\text{depth}-(d-1)$  multi-linear polynomials of  $n$  variables. This  $\text{MOD}_p^A$ -gate, using the Degree Decreasing Lemma (Lemma 6), can be converted to at most  $p^2$   $\text{MOD}_p^A$ -gates, each with  $\text{depth}-(d-1)$  polynomials as inputs, plus (possibly) a leftover  $\text{MOD}_p^A$ -gate with input 1 (which may be connected to the  $\text{MOD}_q^B$  gate with multiple wires) such that the sum of these gates give the same output modulo  $q$  as the original one. If the conversion is done for all  $\text{MOD}_p^A$ -gates, the result is a  $(\text{MOD}_q^B, \text{MOD}_p^A; \text{depth} - (d-1))$  circuit of size at most  $p^2s + 1$ , since the “leftover”  $\text{MOD}_p^A$ -gate with input 1 should be counted once. □

### 4.1 Constant Degree Hypothesis

Barrington, Straubing and Thérien in [3] conjectured that any  $(\text{MOD}_q^B, \text{MOD}_p^A, d)$  circuit needs exponential size to compute the fan-in  $n$  AND function. They called it the *Constant Degree Hypothesis* (CDH), and proved the  $d = 1$  case, with group-theoretic techniques.

Yan and Parberry [21] – using Fourier-analysis – proved also the  $d = 1$  case for  $(\text{MOD}_q^{\{1,2,\dots,q-1\}}, \text{MOD}_2^{\{1\}}; 1)$  circuits, but their method also works for the special case of the CDH where the sum of the degrees of the monomials  $g_i$  on the input-level satisfies:

$$\sum_{\deg(g_i) \geq 1} (\deg(g_i) - 1) \leq \frac{n}{2(q-1)} - O(1).$$

Our Theorem 7 yields the following generalization of this result:

**Theorem 8** *For any prime  $p$  there exists a constant  $0 < c_p < 1$ , such that for any  $0 < c < c_p$  there exists a  $0 < c' < 1$ , such that if a  $(\text{MOD}_q^B, \text{MOD}_p^A, \text{depth} - \lfloor cn \rfloor)$  circuit computes the  $n$ -fan-in AND function, then its size is at least  $2^{c'n}$ .*

**Proof:** From the result of [3] and from Theorem 7 the statement is immediate.  $\square$

We should add, that Theorem 8 does not imply the CDH, but it greatly generalizes the lower bounds of [21] and of [3], and it works not only for the constant degree, but degree- $cn$  polynomials as well.

**Corollary 9** *For any prime  $p$  there exists a constant  $0 < c_p < 1$ , such that for any  $0 < c < c_p$  there exists a  $0 < c' < 1$ , such that if the fan-in  $n$  AND function is computed by a circuit with a  $\text{MOD}_q^B$  gate at the top,  $\text{MOD}_p^A$  gates at the next level, where the input of each  $\text{MOD}_p^A$  gate is an arbitrary integer-valued function of  $cn$  variables plus an arbitrary linear polynomial of  $n$  variables, then the circuit must contain at least  $2^{c'n} \text{MOD}_p^A$  gates.*

**Proof:** First we convert the integer-valued function of  $cn$  variables into a polynomial over  $\text{GF}(p)$ , for each  $\text{MOD}_p^A$  gates. These polynomials have degree at most  $cn$ , and depend on at most  $cn$  variables. Consequently, the circuit is a  $(\text{MOD}_q^B, \text{MOD}_p^A, \text{depth} - (\lfloor cn \rfloor - 1))$  circuit, and Theorem 8 applies.  $\square$

We should mention, that Corollary 9 is much stronger than Yan and Parberry's result [21], since here the degree-sum of the inputs of each  $\text{MOD}_p^A$  gate can be even exponentially large in  $n$ , vs. the small linear upper bound of [21].

### 4.2 The ID function

Krause and Waack [12], using communication-complexity techniques, showed that any  $(\text{MOD}_m^{\{1,2,\dots,m-1\}}, \text{SYMMETRIC}; 1)$  circuit, computing the ID function:

$$\text{ID}(x, y) = \begin{cases} 1, & \text{if } x = y, \\ 0 & \text{otherwise,} \end{cases}$$

for  $x, y \in \{0, 1\}^n$ , should have size at least  $2^n / \log m$ , where SYMMETRIC is a gate, computing an arbitrary symmetric Boolean function.

Using this result, we prove:

**Theorem 10** Let  $p$  and  $q$  be two different primes. If a

$$(\text{MOD}_q^{\{1,2,\dots,m-1\}}, \text{MOD}_p^A, \text{depth} - \lfloor (1 - \varepsilon)n \rfloor)$$

circuit computes the  $2n$ -fan-in ID function, then its size is at least  $2^{c\varepsilon n}$ , where  $0 < c < 1$  depends only on  $p$ .

**Proof:** From the result of [12] and from Theorem 7 the statement is immediate.  $\square$

Unfortunately, the methods of [12] do not generalize for  $\text{MOD}_q^B$  gates with unrestricted  $B$ 's.

### 4.3 The $\text{MOD}_r$ function

Krause and Pudlák [11] proved that any  $(\text{MOD}_{p^k}^{\{0\}}, \text{MOD}_q^{\{0\}}; 1)$  circuit which computes the  $\text{MOD}_r^{\{0\}}$  function has size at least  $2^{c''n}$ , for some  $c'' > 0$ , where  $p, q$  and  $r$  are different primes. We also generalize this result as follows:

**Theorem 11** There exist  $0 < c' < c < 1$  for different primes  $p, q, r$ , and positive integer  $k$ , if circuit  $(\text{MOD}_{p^k}^{\{0\}}, \text{MOD}_q^{\{0\}}; \text{depth} - \lfloor cn \rfloor)$  computes  $\text{MOD}_r^{\{0\}}(x_1, x_2, \dots, x_n)$ , then its size is at least  $2^{c'n}$ .

**Proof:** From the result of [11] and from Theorem 7 the statement is immediate.  $\square$

**Acknowledgment.** The author is indebted to Dániel Varga, Katalin Friedl, Zoltán Király, and Gábor Tardos for fruitful discussions on this work. Supported in part by grants OTKA T030059, FKFP 0607/1999.
