received October 20, 2006, *revised February 21, 2008*, *accepted March 21, 2008*.

For an odd prime p and each non-empty subset $S \subset GF(p)$, consider the hyperelliptic curve X_S defined by $y^2 = f_S(x)$, where $f_S(x) = \prod_{a \in S}(x - a)$. Using a connection between binary quadratic residue codes and hyperelliptic curves over $GF(p)$, this paper investigates how coding theory bounds give rise to bounds such as the following example: for all sufficiently large primes p there exists a subset $S \subset GF(p)$ for which the bound $|X_S(GF(p))| > 1.39p$ holds. We also use the quasi-quadratic residue codes defined below to construct an example of a formally self-dual optimal code whose zeta function does not satisfy the "Riemann hypothesis."

Keywords: binary linear codes, hyperelliptic curves over a finite field, quadratic residue codes, (11T71, 11T24, 14G50, 94B40, 94B27)

A long standing problem has been to develop "good" binary linear codes to be used for error-correction. This paper investigates in some detail an attack on this problem using a connection between quadratic residue codes and hyperelliptic curves. Codes with this kind of relationship have been investigated in Helleseth [H], Bazzi-Mitter [BM], Voloch [V1], and Helleseth-Voloch [HV]. This rest of this introduction is devoted to explaining in more detail the ideas discussed in later sections.

Let $\mathbb{F} = GF(2)$ be the field with two elements and $C \subset \mathbb{F}^n$ denote a binary block code of length n. For any two $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$, let $d(\mathbf{x}, \mathbf{y})$ denote the *Hamming metric*:

$$d(\mathbf{x}, \mathbf{y}) = |\{1 \leq i \leq n \mid x_i \neq y_i\}|. \tag{1}$$

The *weight* $\mathrm{wt}(\mathbf{x})$ of $\mathbf{x}$ is the number of non-zero entries of $\mathbf{x}$. The smallest weight of any non-zero codeword is denoted d - the minimum distance if C is linear. When C is linear, denote the dimension of C by k and call C an $[n, k, d]_2$-code.

Denoting the volume of a Hamming sphere of radius r in $\mathbb{F}^n$ by $V(n, r)$, the binary version of the *Gilbert-Varshamov bound* asserts that (given n and d) there is an $[n, k, d]_2$ code C satisfying $k \geq \log_2(\frac{2^n}{V(n,d-1)})$ [HP].

Conjecture 1 *(Goppa's conjecture [JV],[G]) The binary version of the Gilbert-Varshamov bound is asymptotically exact.*

For each odd prime $p > 5$, a QQR code[(i)] is a linear code of length $2p$. Like the quadratic residue codes, the length and dimension are easy to determine but the minimum distance is more mysterious. In fact, the weight of each codeword can be explicitly computed in terms of the number of solutions in integers mod p to a certain type of ("hyperelliptic") polynomial equation. To explain the results better, some more notation is needed.

For our purposes, a *hyperelliptic curve* X over $GF(p)$ is a polynomial equation of the form $y^2 = h(x)$, where $h(x)$ is a polynomial with coefficients in $GF(p)$ with distinct roots[(ii)]. The number of solutions to $y^2 = h(x) \bmod p$, plus the number of "points at infinity" on X, will be denoted $|X(GF(p))|$. This quantity can be related to a sum of Legendre characters (see Proposition 1 below), thanks to classical work of Artin, Hasse, and Weil. This formula yields good estimates for $|X(GF(p))|$ in many cases (especially when p is large compared to the degree of h). A long-standing problem has been to improve on the trivial estimate when p is small compared to the degree of h. It turns out the work of Tarnanen [T] easily yields some non-trivial information on this problem (see for example Lemma 3 below), but the results given here improve upon this.

For each non-empty subset $S \subset GF(p)$, consider the hyperelliptic curve X_S defined by $y^2 = f_S(x)$, where $f_S(x) = \prod_{a \in S}(x-a)$. Let $B(c,p)$ be the statement: *For all subsets $S \subset GF(p)$, $|X_S(GF(p))| \leq c \cdot p$ holds.* Note that $B(2,p)$ is trivially true, so the statement $B(2-\epsilon, p)$, for some fixed $\epsilon > 0$, might not be horribly unreasonable.

Conjecture 2 ("Bazzi-Mitter conjecture" [BM]) *There is a $c \in (0,2)$ such that, for an infinite number of primes p the statement $B(c,p)$ holds.*

It is remarkable that these two conjectures are related. In fact, using QQR codes we show that if, for an infinite number of primes p with $p \equiv 1 \pmod 4$, $B(1.77, p)$ holds then Goppa's conjecture is false. Although this is a new result, it turns out that it is an easy consequence of the QQR construction given in [BM] if you think about things in the right way. Using LQR codes[(iii)] we will remove the condition $p \equiv 1 \pmod 4$ at a cost of slightly weakening the constant 1.77 (see Corollary 3).

The spectrum and Duursma zeta function of these QQR codes is discussed in Section 3 below and some examples are given (with the help of the software package `SAGE`[S]). We show that the analog of the Riemann hypothesis for the zeta function of an optimal formally self-dual code is false using the family of codes constructed in §2. The section ends with some intriguing conjectures.

We close this introduction with a few open questions which, on the basis of this result, seem natural.

Question 1 *For each prime $p > 5$ is there an effectively computable subset $S \subset GF(p)$ such that $|X_S(GF(p))|$ is "large"?*

Here "large" is left vague but what is intended is some quantity which is unusual. By Weil's estimate (valid for "small"-sized subsets S), we could expect about p points to belong to $|X_S(GF(p))|$. Thus "large" could mean, say, $> c \cdot p$, for some fixed $c > 1$.

The next question is a strong version of the Bazzi-Mitter conjecture.

(i) This code is defined in §2 below.

(ii) This overly simplistic definition brings to mind the famous Felix Klein quote: "Everyone knows what a curve is, until he has studied enough mathematics to become confused through the countless number of possible exceptions." Please see Tsafsman-Vladut [TV] or Schmidt [Sc] for a rigorous treatment.

(iii) These codes will be defined in §4 below.

Question 2 *Does there exist a $c < 2$ such that, for all sufficiently large p and all $S \subset GF(p)$, we have $|X_S(GF(p))| < c \cdot p$?*

In the direction of these questions, a coding theory bound of McEliese-Rumsey-Rodemich-Welsh allows one to establish the following result (see Theorem 3): *There exists a constant p_0 having the following property: if $p \equiv 1 \pmod 4$ and $p > p_0$ then there exists a subset $S \subset GF(p)$ for which the bound $|X_S(GF(p))| > 1.62p$ holds*[(iv)]. Unfortunately, the method of proof gives no clue how to compute p_0 or S. Using the theory of long quadratic-residue codes, we prove the following lower bound (Theorem 6): For all $p > p_0$ there exists a subset $S \subset GF(p)$ for which the bound $|X_S(GF(p))| > 1.39p$ holds. Again, we do not know what p_0 or S is.

Finally, Felipe Voloch [V2] has kindly allowed the author to include some interesting explicit constructions (which do not use any theory of error-correcting codes) in this paper (see §5 below). First, he shows the following result: *If $p \equiv 1 \pmod 8$ then there exists an effectively computable subset $S \subset GF(p)$ for which the bound $|X_S(GF(p))| > 1.5p$ holds.* A similar result holds for $p \equiv 3, 7 \pmod 8$. Second, he gives a construction which answers Question 2 in the negative.

1 Cyclotomic arithmetic mod 2

Let $R = \mathbb{F}[x]/(x^p - 1)$, and let $r_S \in R$ denote the polynomial

$$r_S(x) = \sum_{i \in S} x^i,$$

where $S \subseteq GF(p)$. By convention, if $S = \emptyset$ is the empty set, $r_S = 0$. We define the *weight* of r_S, denoted $\mathrm{wt}(r_S)$, to be the cardinality $|S|$. (In other words, identify in the obvious way each r_S with an element of $\mathbb{F}^p$ and define the weight of r_S to be the Hamming weight of the associated vector.). For the set Q of quadratic residues in $GF(p)^\times$ and the set N of non-quadratic residues in $GF(p)^\times$, we have $\mathrm{wt}(r_Q) = \mathrm{wt}(r_N) = (p-1)/2$. Note that $r_S^2 = r_{2S}$, where $2S$ is the set of elements $2s \in GF(p)$, for $s \in S$. Using this fact and the quadratic reciprocity law, one can easily show that the following are equivalent:

- $r_Q^2 = r_Q$,
- $2 \in Q$
- $p \equiv \pm 1 \pmod 8$.

Moreover, if $2 \in N$ then $r_Q^2 = r_N$.

Let S, S_1, S_2, S_1' denote subsets of $GF(p)$, with $S_1 \cap S_1' = \emptyset$, and let $S^c = GF(p) - S$ denote the complement. For $a \in GF(p)$, let

$$H(S_1, S_2, a) = \{(s_1, s_2) \in S_1 \times S_2 \mid s_1 + s_2 \equiv a \pmod p\}.$$

In particular,

- $H(S_1, S_2, a) = H(S_2, S_1, a)$,

(iv) Moreover, we can remove the hypothesis $p \equiv 1 \pmod 4$ if we assume Conjecture 3.

- there is a natural bijection $H(GF(p), S, a) \cong S$,
- if $S_1 \cap S_1' = \emptyset$ then $H(S_1, S_2, a) + H(S_1', S_2, a) = H(S_1 + S_1', S_2, a)$.

Let

$$h(S_1, S_2, a) = |H(S_1, S_2, a)| \pmod 2.$$

Adding $|H(S_1, S_2, a)| + |H(S_1^c, S_2, a)| = |S_2|$ to $|H(S_1^c, S_2^c, a)| + |H(S_1^c, S_2, a)| = |S_1^c|$, we obtain

$$h(S_1, S_2, a) \equiv h(S_1^c, S_2^c, a) + |S_1^c| + |S_2| \pmod 2. \tag{2}$$

From the definition of r_S,

$$r_{S_1}(x) r_{S_2}(x) = \sum_{a \in GF(p)} h(S_1, S_2, a) x^a$$

in the ring R. Let $* : R \to R$ denote the involution defined by $(r_S)^* = r_{S^c} = r_S + r_{GF(p)}$. We shall see below that this is not an algebra involution.

Lemma 1 *For all $S_1, S_2 \subset GF(p)$, we have*

- *$|S_1|$ odd, $|S_2|$ even: $r_{S_1} r_{S_2} = r_{S_1}^* r_{S_2}^*$ has even weight.*
- *$|S_1|$ even, $|S_2|$ even: $(r_{S_1} r_{S_2})^* = r_{S_1}^* r_{S_2}^*$ has even weight.*
- *$|S_1|$ even, $|S_2|$ odd: $r_{S_1} r_{S_2} = r_{S_1}^* r_{S_2}^*$ has even weight.*
- *$|S_1|$ odd, $|S_2|$ odd: $(r_{S_1} r_{S_2})^* = r_{S_1}^* r_{S_2}^*$ has odd weight.*

This lemma follows from the discussion above by a straightforward argument.

Note that $R_{even} = \{r_S \mid |S| \text{ even}\}$, is a subring of R and, by the previous lemma, $*$ is an algebra involution on R_{even}.

2 QQR Codes

These are some observations on the interesting paper by Bazzi and Mitter [BM]. We shall need to remove the assumption $p \equiv 3 \pmod 8$ (which they make in their paper) below.

If $S \subseteq GF(p)$, let $f_S(x) = \prod_{a \in S}(x - a) \in GF(p)[x]$. Let $\chi = (\frac{\cdot}{p})$ be the quadratic residue character, which is 1 on the quadratic residues $Q \subset GF(p)^\times$, -1 on the quadratic non-residues $N \subset GF(p)^\times$, and is 0 at $0 \in GF(p)$.

Define

$$C_{NQ} = \{(r_N r_S, r_Q r_S) \mid S \subseteq GF(p)\},$$

where N, Q are as above. (We identify in the obvious way each pair $(r_N r_S, r_Q r_S)$ with an element of $\mathbb{F}^{2p}$. In particular, when S is the empty set, $(r_N r_S, r_Q r_S)$ is associated with the the zero vector in $\mathbb{F}^{2p}$.) We call this a *QQR code* (or a *quasi-quadratic residue code*). These are binary linear codes of length $2p$ and dimension

$$k = \begin{cases} p, & \text{if } p \equiv 3 \pmod 4, \\ p-1, & \text{if } p \equiv 1 \pmod 4. \end{cases}$$

This code has no codewords of odd weight, for parity reasons, by Lemma 1.

Remark 1 *If $p \equiv \pm 1 \pmod 8$ then C_{NQ} "contains" a binary quadratic residue code. For such primes p, the minimum distance satisfies the well-known square-root lower bound, $d \geq \sqrt{p}$.*

Based on computations using SAGE, the following statement is likely to be true.

Conjecture 3 *For $p \equiv 1 \pmod 4$, the associated QQR code and its dual satisfy: $C_{NQ} \oplus C_{NQ}^{\perp} = \mathbb{F}^{2p}$, where $\oplus$ stands for the direct product (so, in particular, $C_{NQ} \cap C_{NQ}^{\perp} = \{\mathbf{0}\}$). If $p \equiv 3 \pmod 4$ then the associated QQR code is self-dual: $C_{NQ}^{\perp} = C_{NQ}$.*

The self-dual binary codes have useful upper bounds on their minimum distance (for example, the Sloane-Mallows bound Theorem 9.3.5 in [HP]). Combining this with the lower bound mentioned above, we have the following result.

Lemma 2 *Assume Conjecture 3. If $p \equiv 3 \pmod 4$ then*

$$d \leq 4 \cdot [p/12] + 6.$$

If $p \equiv -1 \pmod 8$ then

$$\sqrt{p} \leq d \leq 4 \cdot [p/12] + 6.$$

Note that these upper bounds (in the cases they are valid) are better than the asymptotic bounds of McEliese-Rumsey-Rodemich-Welsh for rate $1/2$ codes.

Example 1 *The following computations were done with the help of* SAGE. *When $p = 5$, C_{NQ} has weight distribution*

$$[1, 0, 0, 0, 5, 0, 10, 0, 0, 0, 0, 0].$$

When $p = 7$, C_{NQ} has weight distribution

$$[1, 0, 0, 0, 14, 0, 49, 0, 49, 0, 14, 0, 0, 0, 1].$$

When $p = 11$, C_{NQ} has weight distribution

$$[1, 0, 0, 0, 0, 0, 77, 0, 330, 0, 616, 0, 616, 0, 330, 0, 77, 0, 0, 0, 0, 0, 1].$$

When $p = 13$, C_{NQ} has weight distribution

$$[1, 0, 0, 0, 0, 0, 0, 0, 273, 0, 598, 0, 1105, 0, 1300, 0, 598, 0, 182, 0, 39, 0, 0, 0, 0, 0, 0].$$

The following well-known result[(v)] shall be used to estimate the weights of codewords of QQR codes.

Proposition 1 (Artin, Hasse, Weil) *Assume $S \subset GF(p)$ is non-empty.*

[(v)] See for example Weil [W] or Schmidt [Sc], Lemma 2.11.2.

- $|S|$ *even:*

$$\sum_{a \in GF(p)} \chi(f_S(a)) = -p - 2 + |X_S(GF(p))|.$$

- $|S|$ *odd:*

$$\sum_{a \in GF(p)} \chi(f_S(a)) = -p - 1 + |X_S(GF(p))|.$$

- $|S|$ *odd: The genus of the (smooth projective model of the) curve* $y^2 = f_S(x)$ *is* $g = \frac{|S|-1}{2}$ *and*

$$\Big| \sum_{a \in GF(p)} \chi(f_S(a)) \Big| \leq (|S| - 1)p^{1/2} + 1.$$

- $|S|$ *even: The genus of the (smooth projective model of the) curve* $y^2 = f_S(x)$ *is* $g = \frac{|S|-2}{2}$ *and*

$$\Big| \sum_{a \in GF(p)} \chi(f_S(a)) \Big| \leq (|S| - 2)p^{1/2} + 1.$$

Obviously, the last two estimates are only non-trivial for S "small" (e.g., $|S| < p^{1/2}$).

Lemma 3 (Tarnanen [T], Theorem 1) *Fix* τ, $0.39 < \tau < 1$. *For all sufficiently large* p, *the following statement is false: For all subsets* $S \subset GF(p)$ *with* $|S| \leq \tau p$, *we have* $0.42p < |X_S(GF(p))| < 1.42p$.

Remark 2 (1) *Here the meaning of "sufficiently large" is hard to make precise. The results of Tarnanen are actually asymptotic (as* $p \to \infty$*), so we can simply say that the negation of part (1) of this Lemma contradicts Theorem 1 in [T].*
(2) *This Lemma does not seem to imply "*$B(1.42, p)$ *is false, for sufficiently large* p*" (so Theorem 6 below is a new result), though it would if the condition* $0.42p < |X_S(GF(p))|$ *could be eliminated. Also of interest is the statement about character sums in Theorem 1 of Stepanov [St].*

Proof: This is an immediate consequence of the Proposition above and Theorem 1 in [T]. □

Lemma 4 (Bazzi-Mitter [BM], Proposition 3.3) *Assume* 2 *and* -1 *are quadratic non-residues mod* p *(i.e.* $p \equiv 3 \pmod 8$*).*

If $\mathbf{c} = (r_N r_S, r_Q r_S)$ *is a nonzero codeword of the* $[2p, p]$ *binary code* C_{NQ} *then the weight of this codeword can be expressed in terms of a character sum as*

$$\mathrm{wt}(\mathbf{c}) = p - \sum_{a \in GF(p)} \chi(f_S(a)),$$

if $|S|$ *is even, and*

$$\mathrm{wt}(\mathbf{c}) = p + \sum_{a \in GF(p)} \chi(f_{S^c}(a)),$$

if $|S|$ *is odd.*

In fact, looking carefully at their proof, one finds the following result.

Proposition 2 *Let* $\mathbf{c} = (r_N r_S, r_Q r_S)$ *be a nonzero codeword of* C_{NQ}.

(a) If $|S|$ *is even*

$$\mathrm{wt}(\mathbf{c}) = p - \sum_{a \in GF(p)} \chi(f_S(a)) = 2p + 2 - |X_S(GF(p))|.$$

(b) If $|S|$ *is odd and* $p \equiv 1 \pmod 4$ *then the weight is*

$$\mathrm{wt}(\mathbf{c}) = p - \sum_{a \in GF(p)} \chi(f_{S^c}(a)) = 2p + 2 - |X_{S^c}(GF(p))|.$$

(c) If $|S|$ *is odd and* $p \equiv 3 \pmod 4$ *then*

$$\mathrm{wt}(\mathbf{c}) = p + \sum_{a \in GF(p)} \chi(f_{S^c}(a)) = |X_{S^c}(GF(p))| - 2.$$

Proof: If $A, B \subseteq GF(p)$ then the discussion in §1 implies

$$\mathrm{wt}(r_A r_B) = \sum_{k \in GF(p)} \text{ parity } |A \cap (k - B)|, \tag{3}$$

where $k - B = \{k - b \mid b \in B\}$ and parity$(x) = 1$ if x is an odd integer, and $= 0$ otherwise. Let $S \subseteq GF(p)$, then we have

$$p - \mathrm{wt}(r_Q r_S) - \mathrm{wt}(r_N r_S) = \sum_{a \in GF(p)} \big(1 - \text{ parity } |Q \cap (a - S)| - \text{ parity } |N \cap (a - S)|\big).$$

Let

$$T_a(S) = 1 - \text{ parity } |Q \cap (a - S)| - \text{ parity } |N \cap (a - S)|.$$

Case 1. If $|S|$ is even and $a \in S$ then $0 \in a - S$ so $|Q \cap (a - S)|$ odd implies that $|N \cap (a - S)|$ is even, since 0 is not included in $Q \cap (a - S)$ or $N \cap (a - S)$. Likewise, $|Q \cap (a - S)|$ even implies that $|N \cap (a - S)|$ is odd. Therefore $T_a(S) = 0$.

Case 2. If $|S|$ is even and $a \notin S$ then parity $|Q \cap (a - S)|$ =parity$|N \cap (a - S)|$. If $|Q \cap (a - S)|$ is even then $T_a(S) = 1$ and if $|Q \cap (a - S)|$ is odd then $T_a(S) = -1$.

Case 3. $|S|$ is odd. We claim that $(a - S)^c = a - S^c$. (Proof: Let $s \in S$ and $\bar{s} \in S^c$. Then $a - s = a - \bar{s} \implies s = \bar{s}$, which is obviously a contradiction. Therefore $(a - S) \cap (a - S^c) = \emptyset$, so $(a - S)^c \supseteq (a - S^c)$. Replace S by S^c to prove the claim.)

Also note that

$$\big(Q \cap (a - S)\big) \sqcup \big(Q \cap (a - S^c)\big) = GF(p) \cap Q = Q$$

has $|Q| = \frac{p-1}{2}$ elements ($\sqcup$ denotes disjoint union). So

$$\text{parity } |Q \cap (a - S)| = \text{parity } |Q \cap (a - S^c)|$$

if and only if $|Q|$ is even and

$$\text{parity } |Q \cap (a - S)| \neq \text{parity } |Q \cap (a - S^c)|$$

if and only if $|Q|$ is odd.

Conclusion

$$|S| \text{ even: } T_a(S) = \prod_{x \in a - S} \left(\frac{x}{p}\right),$$

$$|S| \text{ odd and } p \equiv 3 \pmod 4\text{: } T_a(S) = -T_a(S^c),$$

$$|S| \text{ odd and } p \equiv 1 \pmod 4\text{: } T_a(S) = T_a(S^c).$$

The relation between $\text{wt}(\mathbf{c})$ and the character sum follows from this. For the remaining part of the equation, use Proposition 1. □

Remark 3 *It can be shown, using the coding-theoretic results above, that if $p \equiv -1 \pmod 8$ then (for non-empty S) $X_S(GF(p))$ contains at least $\sqrt{p} + 1$ points. This also follows from Weil's estimate, but since the proof is short, it is given here.*

What part c of Proposition 2 gives is that if $p \equiv -1 \pmod 8$ and $|S|$ is odd then $X_S(GF(p))$ contains at least $\sqrt{p}+2$ points. If $|S|$ is even then perform the substitution $x = a+1/\overline{x}$, $y = \overline{y}/\overline{x}^{|S|}$ on the equation $y^2 = f_S(x)$. This creates a hyperelliptic curve X in $(\overline{x}, \overline{y})$ for which $|X(GF(p))| = |X_S(GF(p))|$ and $X \cong X_{S'}$, where $|S'| = |S| - 1$ is odd. Now apply part 3 of the above proposition and Remark 1 to $X_{S'}$. □

Remark 4 *If $|S| = 2$ or $|S| = 3$ then more can be said about the character sums above.*

If $|S| = 2$ then $\sum_a \chi(f_S(a))$ can be computed explicitly (it is "usually" equal to -1 - see Proposition 1 in [Wa]). If $|S| = 3$ then $\sum_a \chi(f_S(a))$ can be expressed in terms of a hypergeometric function ${}_2F_1$ over $GF(p)$ (see Proposition 2 in [Wa]).

It has already been observed that the following fact is true. Since its proof using basic facts about hyperelliptic curves is so short, it is included here.

Corollary 1 *C_{NQ} is an even weight code.*

Proof: Since p is odd $1 \neq -1$ in $GF(p)$, so every affine point in $X_S(GF(p))$ occurs as an element of a pair of solutions of $y^2 = f_S(x)$. There are two points at infinity (if ramified, it is counted with multiplicity two), so in general $|X_S(GF(p))|$ is even. The formulas for the weight of a codeword in the above Proposition imply every codeword has even weight. □

As a consequence of this Proposition and Lemma 2, we have the following result.

Corollary 2 *Assume Conjecture 3. If* $p \equiv 3 \pmod 4$ *then* $\max_S |X_S(GF(p))| > \frac{5}{3}p - 4$.

Example 2 *The following examples were computed with the help of* SAGE.

If $p = 11$ *and* $S = \{1, 2, 3, 4\}$ *then*

$$(r_S(x)r_N(x), r_S(x)r_Q(x)) = (x^{10} + x^9 + x^7 + x^6 + x^5 + x^4 + x^2 + 1, x^{10} + x^9 + x^7 + x^6 + x^5 + x^3 + x + 1),$$

corresponds to the codeword $(1, 0, 1, 0, 1, 1, 1, 1, 0, 1, 1, 1, 1, 0, 1, 0, 1, 1, 1, 0, 1, 1)$ *of weight* 16*. An explicit computation shows that the character sum* $\sum_{a \in GF(11)} \chi(f_S(a))$ *is* -5*, as expected.*

If $p = 11$ *and* $S = \{1, 2, 3\}$ *then*

$$(r_S(x)r_N(x), r_S(x)r_Q(x)) = (x^9 + x^7 + x^5 + x^4 + x^3 + x^2 + x, x^{10} + x^8 + x^6 + x^3 + x^2 + x + 1).$$

corresponds to the codeword $(0, 1, 1, 1, 1, 1, 0, 1, 0, 1, 0, 1, 1, 1, 1, 0, 0, 1, 0, 1, 0, 1)$ *of weight* 14*. An explicit computation shows that the character sum* $\sum_{a \in GF(11)} \chi(f_{S^c}(a))$ *is* 3*, as predicted.*

Recall $B(c, p)$ is the statement: $|X_S(GF(p))| \leq c \cdot p$ for all $S \subset GF(p)$.

Theorem 1 (Bazzi-Mitter) *Fix* $c \in (0, 2)$*. If* $B(c, p)$ *holds for infinitely many* p *with* $p \equiv 1 \pmod 4$ *then there exists an infinite family of binary codes with asymptotic rate* $R = 1/2$ *and relative distance* $\delta \geq 1 - \frac{c}{2}$.

This is an easy consequence of the above Proposition and is essentially in [BM] (though they assume $p \equiv 3 \pmod 8$).

Theorem 2 *If* $B(1.77, p)$ *is true for infinitely many primes* p *with* $p \equiv 1 \pmod 4$ *then Goppa's conjecture is false.*

Proof: Recall Goppa's conjecture is that the binary asymptotic Gilbert-Varshamov bound is best possible for any family of binary codes. The asymptotic GV bound states that the rate R is greater than or equal to $1 - H_2(\delta)$, where

$$H_q(\delta) = \delta \cdot \log_q(q - 1) - \delta \log_q(\delta) - (1 - \delta) \log_q(1 - \delta)$$

is the entropy function (for a q-ary channel). Therefore, according to Goppa's conjecture, if $R = \frac{1}{2}$ (and $q = 2$) then the best possible δ is $\delta_0 = .11$. Assume $p \equiv 1 \pmod 4$. Goppa's conjecture implies that the minimum distance of our QQR code with rate $R = \frac{1}{2}$ satisfies $d < \delta_0 \cdot 2p = .22p$, for sufficiently large p. Recall that the weight of a codeword in this QQR code is given by Proposition 2. $B(1.77, p)$ (with $p \equiv 1 \pmod 4$) implies (for all $S \subset GF(p)$) $\mathrm{wt}((r_S r_N, r_S r_Q)) \geq 2p - |X_S(GF(p))| \geq 0.23p$. In other words, for $p \equiv 1 \pmod 4$, all nonzero codewords have weight at least $0.23p$. This contradicts the estimate above. □

Using the same argument and the first McEliese-Rumsey-Rodemich-Welsh (MRRW) bound ([HP], Theorem 2.10.6), we prove the following unconditional result.

Theorem 3 *For all sufficiently large primes p for which $p \equiv 1 \pmod 4$, the statement $B(1.62, p)$ is false.*

Proof: If a prime p satisfies $B(1.62, p)$ then we shall call it "admissible." We show that the statement "$B(1.62, p)$ holds for all sufficiently large primes p for which $p \equiv 1 \pmod 4$" contradicts the first asymptotic MRRW bound. Indeed, this MRRW bound states that the rate R is less than or equal to

$$h(\delta) = H_2(\frac{1}{2} - \sqrt{\delta(1-\delta)}).$$

This, and the fact that $R = \frac{1}{2}$ for our QQR codes (with $p \equiv 1 \pmod 4$), imply $\delta \leq \delta_0 = h^{-1}(1/2) \cong 0.187$. Therefore, for all large p (admissible or not), $d \leq \delta_0 \cdot 2p$. On the other hand, if p is admissible and $|X_S(GF(p))| \leq c \cdot p$ (where $c = 1.62$) then by the above argument, $d \geq 2 \cdot (p - \frac{c}{2}p)$. Together, we obtain $1 - \frac{c}{2} \leq \delta_0$, so $c \geq 2 \cdot (1 - h^{-1}(1/2)) \cong 1.626$. This is a contradiction. □

Corollary 3 *Assume Conjecture 3. There is a constant p_0 (ineffectively computable) having the following property: if $p > p_0$ then there is a subset $S \subset GF(p)$ for which the bound $|X_S(GF(p))| > 1.62p$ holds.*

This is of course the same as the above theorem, except that we have used Corollary 2 (which unfortunately depends on Conjecture 3) to remove the hypothesis $p \equiv 1 \pmod 4$.

3 Weight distributions

In [D1] Iwan Duursma associates to a linear code C over $GF(q)$ a *zeta function* $Z = Z_C$ of the form

$$Z(T) = \frac{P(T)}{(1-T)(1-qT)},$$

where $P(T)$ is a polynomial of degree $n + 2 - d - d^\perp$ which only depends on C through its weight enumerator polynomial (here d is the minimum distance of C and $d^\perp$ is the minimum distance of its dual code $C^\perp$; we assume $d \geq 2$ and $d^\perp \geq 2$). If $\gamma = \gamma(C) = n+k+1-d$ and $z_C(T) = Z_C(T)T^{1-\gamma}$ then the functional equation in [D1] can be written in the form $z_{C^\perp}(T) = z_C(1/qT)$. If we let $\zeta_C(s) = Z_C(q^{-s})$ and $\xi_C(s) = z_C(q^{-s})$ then ζ_C and ξ_C have the same zeros but ξ_C is "more symmetric" since the functional equation expressed in terms of it becomes

$$\xi_{C^\perp}(s) = \xi_C(1-s).$$

Abusing terminology, we call both Z_C and ζ_C a *Duursma zeta function*. In fact, if ρ_i denotes the i-th zero of the zeta function $Z(T)$ of an actual code then equations (5)-(6) of [D2] implies (for the even weight binary codes we are considering here) the relation

$$d = 2 - \sum_i \rho_i^{-1}.$$

Therefore, further knowledge of the zeros of $Z(T)$ could be very useful.

If C is self-dual (or actually only formally self-dual) then the zeros of the ζ-function occur in pairs about the "critical line" $Re(s) = \frac{1}{2}$. Following Duursma, we say (for formally self-dual codes C) the zeta function ζ_C satisfies the *Riemann hypothesis* if all its zeros occur on the "critical line".

Example 3 *The following computations were done with the help of* SAGE. *If* $p = 7$ *then the* $[14, 7, 4]$ *(self-dual) code* C_{NQ} *has "zeta polynomial"*

$$P(T) = \frac{2}{143} + \frac{4}{143}T + \frac{19}{429}T^2 + \frac{28}{429}T^3 + \frac{40}{429}T^4 + \frac{56}{429}T^5 + \frac{76}{429}T^6 + \frac{32}{143}T^7 + \frac{32}{143}T^8.$$

It can be checked that all the roots ρ *of* Z_C *have* $|\rho| = 1/\sqrt{2}$*, thus verifying the Riemann hypothesis in this case.*

It would be interesting to know if the Duursma zeta function $Z(T)$ of C_{NQ}, for $p \equiv 3 \pmod 4$, always satisfies the Riemann hypothesis.

A self-dual code is called *extremal* if its minimum distance satisfies the Sloane-Mallows bound [D3] and *optimal* if its minimum distance is maximal among all such linear codes of that length and dimension (see also Chinen [Ch1], [Ch2]). As noted above, the Duursma zeta function only depends on the weight enumerator. It has been conjectured that, for all extremal self-dual codes C, the ζ-function satisfies the Riemann hypothesis. The example below shows that "extremal self-dual" cannot be replaced by "optimal formally self-dual".

Based on computer computations using SAGE, the following statement appears to be true, though we have no proof.

Conjecture 4 *If* $p \equiv 1 \pmod 4$ *then the code* C' *spanned by* C_{NQ} *and the all ones codeword (i.e., the smallest code containing* C_{NQ} *and all its complementary codewords) is a formally self-dual code of dimension* p*. Moreover, if* $A = [A_0, A_1, ..., A_n]$ *denotes the weight distribution vector of* C_{NQ} *then the weight distribution vector of* C' *is* $A + A^*$*, where* $A^* = [A_n, ..., A_1, A_0]$.

Using SAGE, it can be shown that the Riemann hypothesis is not valid for these "extended QQR codes" in general, as the following example illustrates.

Example 4 *If* $p = 13$ *then* C' *is a* $[26, 13, 6]$ *code with weight distribution*

$$[1, 0, 0, 0, 0, 0, 39, 0, 455, 0, 1196, 0, 2405, 0, 2405, 0, 1196, 0, 455, 0, 39, 0, 0, 0, 0, 0, 1].$$

This is (by coding theory tables, as included in SAGE*) an optimal, formally self-dual code. This code* C' *has zeta polynomial*

$$\begin{aligned} P(T) \quad &= \tfrac{3}{17710} + \tfrac{6}{8855}T + \tfrac{611}{336490}T^2 + \tfrac{9}{2185}T^3 + \tfrac{3441}{408595}T^4 + \tfrac{6448}{408595}T^5 + \tfrac{44499}{1634380}T^6 \\ &+ \tfrac{22539}{520030}T^7 + \tfrac{66303}{1040060}T^8 + \tfrac{22539}{260015}T^9 + \tfrac{44499}{408595}T^{10} + \tfrac{51584}{408595}T^{11} \\ &+ \tfrac{55056}{408595}T^{12} + \tfrac{288}{2185}T^{13} + \tfrac{19552}{168245}T^{14} + \tfrac{768}{8855}T^{15} + \tfrac{384}{8855}T^{16}. \end{aligned}$$

Using SAGE*, it can be checked that only 8 of the 12 zeros of this function have absolute value* $1/\sqrt{2}$.

4 Long Quadratic Residue Codes

We now introduce a new code, constructed similarly to the QQR codes discussed above:

$$C = \{(r_N r_S, r_Q r_S, r_N r_S^*, r_Q r_S^*) \mid S \subseteq GF(p)\}.$$

We call this a *long quadratic residue code*, or ***LQR code*** for short, and identify it with a subset of $\mathbb{F}^{4p}$. Observe that this code is non-linear.

For any $S \subseteq GF(p)$, let

$$\mathbf{c}_S = (r_N r_S, r_Q r_S, r_N r_S^*, r_Q r_S^*)$$

and let

$$v_S = (r_N r_S, r_Q r_S, r_N r_S, r_Q r_S).$$

If $S_1 \Delta S_2$ denotes the symmetric difference between S_1 and S_2 then it is easy to check that

$$\mathbf{c}_{S_1} + \mathbf{c}_{S_2} = v_{S_1 \Delta S_2}. \tag{4}$$

We now compute the size of C using Lemma 1. We prove the *claim*: if $p \equiv 3 \pmod 4$ then the map that sends S to the codeword $\mathbf{c}_S$ is injective. This implies $|C| = 2^p$. Suppose not, then there are two subsets $S_1,\ S_2 \subseteq GF(p)$ that are mapped to the same codeword. Subtracting $\mathbf{c}_{S_1} - \mathbf{c}_{S_2} = \mathbf{c}_{S_1} + \mathbf{c}_{S_2} = v_{S_1 \Delta S_2}$, and the subset $T = S_1 \Delta S_2$ satisfies $r_Q r_T = r_N r_T = r_Q r_{T^c} = r_N r_{T^c} = 0$. If $|T|$ is even then $0 = (r_Q + r_N) r_T = (r_{GF(p)} - 1) r_T = r_T$. This forces T to be the empty set, so $S_1 = S_2$. Now if $|T|$ is odd then similar reasoning implies that T^c is the empty set. Therefore, $S_1 = \emptyset$ and $S_2 = GF(p)$ or vice versa. This proves the claim.

In case $p \equiv 1 \pmod 4$, we *claim*: $|C| = 2^{p-1}$. Again, suppose there are two subsets $S_1,\ S_2 \subseteq GF(p)$ that are mapped to the same codeword. Then the subset $T = S_1 \Delta S_2$ satisfies $r_Q r_T = r_N r_T = r_Q r_{T^c} = r_N r_{T^c} = 0$. This implies either $T = \emptyset$ or $T = GF(p)$. Therefore, either $S_1 = S_2$ or $S_1 = S_2^c$.

Combining this discussion with Proposition 1, we have proven the following result.

Theorem 4 *The code C has length $n = 4p$ and has size $M = 2^{p-1}$ if $p \equiv 1 \pmod 4$, and size $M = 2^p$ if $p \equiv 3 \pmod 4$. If $p \equiv 3 \pmod 4$ then the minimum non-zero weight is $2p$ and the minimum distance is at least*

$$d_p = 4p - 2 \max_{S \subset GF(p)} |X_S(GF(p))|.$$

If $p \equiv 1 \pmod 4$ then C is a binary $[4p, p-1, d_p]$-code.

Remark 5 *If $p \equiv 3 \pmod 4$, there is no simple reason I can think of why the minimum distance should actually be less than the minimum non-zero weight.*

Lemma 5 *If $p \equiv 1 \pmod 4$ then*

- $v_S = \mathbf{c}_S$,
- $\mathbf{c}_{S_1} + \mathbf{c}_{S_2} = \mathbf{c}_{S_1 \Delta S_2}$,
- *the code C is isomorphic to the QQR code C_{NQ}.*

In particular, C is linear and of dimension $p-1$.

Proof: It follows from the the proof of Theorem 4 that if $p \equiv 1 \pmod 4$ then $r_N r_{S_1} = r_N r_{S_2}$ and $r_Q r_{S_1} = r_Q r_{S_2}$ if and only if $S_2 = S_1^c$. The lemma follows rather easily as a consquence of this and (4). □

Assume $p \equiv 3 \pmod 4$. Let

$$V = \{v_S \mid S \subset GF(p)\}$$

and let

$$\overline{C} = C \cup V.$$

Lemma 6 *The code $\overline{C}$ is*

1. *the smallest linear subcode of $\mathbb{F}^{4p}$ containing C,*
2. *dimension $p+1$,*
3. *minimum distance $\min(d_p, 2p)$.*

By abuse of terminology, we call $\overline{C}$ an *LQR code*.

Proof: Part 1 follows from (4). Part 2 follows from a counting argument (as in the proof of Theorem 4). Part 3 is a corollary of Theorem 4. □

Recall that

$$\mathrm{wt}(r_N r_S, r_Q r_S) = \begin{cases} p - \sum_{a \in GF(p)} \left(\frac{f_S(a)}{p}\right), & |S| \text{ even (any } p), \\ p - \sum_{a \in GF(p)} \left(\frac{f_{S^c}(a)}{p}\right), & |S| \text{ odd and } p \equiv 1 \pmod 4, \\ p + \sum_{a \in GF(p)} \left(\frac{f_{S^c}(a)}{p}\right), & |S| \text{ odd and } p \equiv 3 \pmod 4, \end{cases}$$

by Proposition 2.

Lemma 7 *For each p, the codeword $\mathbf{c}_S = (r_N r_S, r_Q r_S, r_N r_S^*, r_Q r_S^*)$ of C has weight*

$$\mathrm{wt}(\mathbf{c}_S) = \begin{cases} 2p - 2\sum_{a \in GF(p)} \left(\frac{f_S(a)}{p}\right), & p \equiv 1 \pmod 4, \\ 2p, & p \equiv 3 \pmod 4. \end{cases}$$

In other words, if $p \equiv 3 \pmod 4$ then C is a constant weight code.

Proof: Indeed, Proposition 2 implies if $p \equiv 1 \pmod 4$ then

$$\begin{aligned} \mathrm{wt}\left(r_N r_S, r_Q r_S, r_N r_S^*, r_Q r_S^*\right) &= \mathrm{wt}\left(r_N r_S, r_Q r_S\right) + \mathrm{wt}\left(r_N r_S^*, r_Q r_S^*\right) \\ &= 2 \cdot \mathrm{wt}\left(r_N r_S, r_Q r_S\right) \\ &= 2p - 2\sum_{a \in GF(p)} \left(\frac{f_S(a)}{p}\right), \end{aligned} \tag{5}$$

if $p \equiv 3 \pmod 4$ and $|S|$ is even then

$$\begin{aligned} \mathrm{wt}\,(r_N r_S, r_Q r_S, r_N r_S^*, r_Q r_S^*) &= \mathrm{wt}\,(r_N r_S, r_Q r_S) + \mathrm{wt}\,(r_N r_S^*, r_Q r_S^*) \\ &= p - \sum_{a \in GF(p)} \left(\frac{f_S(a)}{p}\right) + p + \sum_{a \in GF(p)} \left(\frac{f_S(a)}{p}\right) \\ &= 2p, \end{aligned} \tag{6}$$

and if $p \equiv 3 \pmod 4$ and $|S|$ is odd then

$$\begin{aligned} \mathrm{wt}\,(r_N r_S, r_Q r_S, r_N r_S^*, r_Q r_S^*) &= \mathrm{wt}\,(r_N r_S, r_Q r_S) + \mathrm{wt}\,(r_N r_S^*, r_Q r_S^*) \\ &= p + \sum_{a \in GF(p)} \left(\frac{f_S(a)}{p}\right) + p - \sum_{a \in GF(p)} \left(\frac{f_S(a)}{p}\right) \\ &= 2p. \end{aligned} \tag{7}$$

□

Example 5 *The following examples were computed with the help of* SAGE. *When* $p = 11$ *and* $S = \{1, 2, 3, 4\}$, $\mathbf{c}_S$ *corresponds to the codeword*

$$(0, 1, 1, 1, 1, 1, 0, 1, 0, 1, 0, 1, 1, 1, 1, 1, 0, 0, 1, 0, 1, 0, 1, 1, 0, 0, 0, 0, 0, 1, 0, 1, 0, 1, 0, 0, 0, 0, 0, 1, 1, 0, 1, 0, 1, 0)$$

of weight 22. *When* $p = 11$ *and* $S = \{1, 2, 3\}$, $\mathbf{c}_S$ *corresponds to the codeword*

$$(1, 0, 1, 0, 1, 1, 1, 1, 0, 1, 1, 1, 1, 0, 1, 0, 1, 1, 1, 0, 1, 1, 0, 1, 0, 1, 0, 0, 0, 0, 1, 0, 0, 0, 0, 1, 0, 1, 0, 0, 0, 1, 0, 0)$$

of weight 22.

It turns out Lemma 6 allows us to improve the statement of Theorem 2 in §2. The next subsection is devoted to this goal.

4.1 Goppa's conjecture revisited

We shall now remove the condition $p \equiv 1 \pmod 4$ in one of the results in §2, at a cost of weakening the constant involved.

Assuming $B(c, p)$ holds, we have that the minimum distance of $\overline{C}$ is $\geq \min(d_p, 2p) \geq 4p(1 - \frac{c}{2})$ and the information rate is $R = \frac{1}{4} + \frac{1}{4p}$. When $R = 1/4$, Goppa's conjecture gives $\delta = 0.214...$. So Goppa's conjecture will be false if $1 - \frac{c}{2} = 0.215$, or $c = 1.57$. We have the following improvement of Theorem 2.

Theorem 5 *If the* $B(1.57, p)$ *is true for infinitely many primes* p *then Goppa's conjecture is false.*

A similar argument (using $h(x)$ and the MRRW bound in place of $1 - H_2(x)$ and the hypothetical Goppa bound) gives

Theorem 6 $B(1.39, p)$ *cannot be true for infinitely many primes* p. *In other words, for all "sufficiently large"* p, *we must have* $X_S(GF(p)) > 1.39p$ *for some* $S \subset GF(p)$.

5 Some results of Voloch

Lemma 8 (Voloch) *If $p \equiv 1, 3 \pmod 8$ then $|X_Q(GF(p))| = 1.5p + a$, where Q is the set of quadratic residues and a is a small constant, $-\frac{1}{2} \leq a \leq \frac{5}{2}$.*

A similar bound holds if X_Q is replaced by X_N and $p \equiv 1, 3 \pmod 8$ is replaced by $p \equiv 7 \pmod 8$ (in which case 2 is a quadratic residue).

Proof: By Proposition 1, we know that if $p \equiv 3 \pmod 8$ (so $|Q|$ is odd):

$$\sum_{a \in GF(p)} \chi(f_Q(a)) = -p - 1 + |X_Q(GF(p))|.$$

Similarly, if $p \equiv 1 \pmod 8$ (so $|Q|$ is even):

$$\sum_{a \in GF(p)} \chi(f_Q(a)) = -p - 2 + |X_Q(GF(p))|.$$

Since $b^{\frac{p-1}{2}} \equiv \chi(b) \pmod p$, we have

$$x^{\frac{p-1}{2}} - 1 = \prod_{a \in Q} (x - a) = f_Q(x), \quad x^{\frac{p-1}{2}} + 1 = \prod_{a \in N} (x - a).$$

In particular, for all $n \in N$,

$$f_Q(n) = \prod_{a \in Q} (n - a) = n^{\frac{p-1}{2}} - 1 \equiv -2 \pmod p.$$

Since $p \equiv 1, 3 \pmod 8$, we have $\chi(-2) = 1$, so $\chi(f_Q(n)) = 1$ for all $n \in N$. It follows that $|X_Q(GF(p))| = \frac{3}{2}p + \chi(f_Q(0)) + \frac{1}{2}$ (if $p \equiv 3 \pmod 8$) or $|X_Q(GF(p))| = \frac{3}{2}p + \chi(f_Q(0)) + \frac{3}{2}$ (if $p \equiv 1 \pmod 8$). □

Here is an extension of the idea in the above proof. Fix an integer $\ell > 2$. Assuming ℓ divides $p - 1$, there are distinct ℓ-th roots $r_1 = 1, r_2, ..., r_\ell$ in $GF(p)$ for which $x^{p-1} - 1 = \prod_{i=1}^{\ell} (x^{\frac{p-1}{\ell}} - r_i)$. Also, $x^{\frac{p-1}{\ell}} - 1 = \prod_{a \in P_\ell} (x - a) = f_{P_\ell}(x)$, where P_ℓ denotes the set of non-zero ℓ-th powers in $GF(p)$.

Claim: It is possible to find an infinite sequence of primes p satisfying $p \equiv 1 \pmod \ell$ and $\chi(r_i - 1) = 1$, for all $2 \leq i \leq \ell$ (where χ denotes the Legendre character mod p). If the claim is true then we will have a lower bound for $|X_{P_\ell}(GF(p))|$ on the order of $(2 - \frac{1}{\ell})p$, along the lines above, by Proposition 1.

Proof of claim: It is a well-known fact in algebraic number theory that $p \equiv 1 \pmod \ell$ implies that the prime p splits completely in the cyclotomic field $\mathbb{Q}_\ell$ generated by the ℓ-th roots of unity in $\mathbb{C}$, denoted $\tilde{r}_1 = 1, \tilde{r}_2, ..., \tilde{r}_\ell$. The condition $\chi(r_i - 1) = 1$ means that p splits in the extension of $\mathbb{Q}_\ell$ obtained by adjoining $\sqrt{\tilde{r}_i - 1}$ (here $i = 2, ..., \ell$). By Chebotarev's density theorem there exist infinitely many such p, as claimed. □

In fact, there are effective versions which give explicit information on computing such p [LO], [Se]. This, together with the previous lemma, proves the following result.

Theorem 7 (Voloch) *If $\ell \geq 2$ is any fixed integer then for infinitely many primes p there exists a subset $S \subset GF(p)$ for which $|X_S(GF(p))| = (2 - \frac{1}{\ell})p + a$, where a is a small constant, $-\frac{1}{2} \leq a \leq \frac{5}{2}$.*

In fact, the primes occurs with a positive (Dirichlet) density and the set S can be effectively constructed.

Acknowledgements

I thank Prof. Amin Shokrollahi of the Ecole Polytechnique Fédérale de Lausanne for helpful advice and Prof. Felipe Voloch of the University of Texas for allowing his construction to be included above. Parts of this note (such as Proposition 2) can be found in the honors thesis [C] of my former student Greg Coy, who was a pleasure to work with. Last but not least, I thank the anonymous referees who substantially improved the paper with their insightful suggestions.
