For a binary code Γ of length v, a v-word w produces by a set of codewords $\{w^1, \ldots, w^r\} \subseteq \Gamma$ if for all $i = 1, \ldots, v$, we have $w_i \in \{w_i^1, \ldots, w_i^r\}$. We call a code r-secure frameproof of size t if $|\Gamma| = t$ and for any v-word that is produced by two sets C_1 and C_2 of size at most r, then the intersection of these sets is non-empty. A d-biclique cover of size v of a graph G is a collection of v complete bipartite subgraphs of G such that each edge of G belongs to at least d of these complete bipartite subgraphs. In this paper, we show that for $t \geq 2r$, an r-secure frameproof code of size t and length v exists if and only if there exists a 1-biclique cover of size v for the Kneser graph $\mathrm{KG}(t, r)$ whose vertices are all r-subsets of a t-element set and two r-subsets are adjacent if their intersection is empty. Then we investigate some connection between the minimum size of d-biclique covers of Kneser graphs and cover-free families, where an $(r, w; d)$ cover-free family is a family of subsets of a finite set X such that the intersection of any r members of the family contains at least d elements that are not in the union of any other w members. The minimum size of a set X for which there exists an $(r, w; d)$ cover-free family with t blocks is denoted by $N((r, w; d), t)$. We prove that for $t > 2r$ and $r > s$, we have $bc_d(\mathrm{KG}(t, r)) \geq bc_m(\mathrm{KG}(t, s))$, where $m = N((r - s, r - s; d), t - 2s)$. Finally, we show that for any $1 \leq i < r$, $1 \leq j < w$, and $t \geq r + w$ we have $N((r, w; d), t) \geq N((r - i, w - j; m), t)$, where $m = N((i, j; d), t - r - w + i + j)$.

Keywords: cover-free family, secure frameproof code, biclique cover, Hadamard matrix

1 Introduction

Illegal copy is a major problem in digital data. *Frameproof codes* are one of many different techniques to prevent products against illegal copy that were first introduced by Boneh and Shaw [2]. To protect digital data, the distributor marks each copy uniquely with a codeword. These codewords have the property that an illegal copy can trace and back to the buyer. Also, these marks are impossible to remove or change for non-colluding buyers. But, whenever some malicious buyers (that are called pirates) are colluding, they can compare their copies and detect different positions. Colluding buyers have the ability to erase or change detected positions and construct some illegal marks. In order to formulate these conditions we

consider the following definitions and notations.
Let $\Gamma \subseteq \{0,1\}^v$ and $|\Gamma| = t$. Γ is called a (v,t)-code and every element of Γ is said to be a codeword. We write w_i for the ith component of a word w. Also, the incidence matrix of Γ is a $t \times v$ matrix whose rows are the codewords in Γ. Suppose $C = \{w^{(u_1)}, w^{(u_2)}, \ldots, w^{(u_d)}\} \subseteq \Gamma \subseteq \{0,1\}^v$. For $i \in \{1,2,\ldots,v\}$, the ith component is said undetectable for the coalition C if

$$w_i^{(u_1)} = w_i^{(u_2)} = \cdots = w_i^{(u_d)}.$$

Let $U(C)$ be the set of undetectable components for C. The set

$$F(C) = \{x \in \{0,1\}^v : x|_{U(C)} = w^{(u_i)}|_{U(C)} \text{ for all } w^{(u_i)} \in C\}$$

represents all possible v-tuples that could be produced by the coalition C by comparing the d codewords.

Definition 1 *An r-frameproof code is a subset $\Gamma \subseteq \{0,1\}^v$ such that for every $C \subseteq \Gamma$ where $|C| \leq r$, we have $F(C) \cap \Gamma = C$.*

Let $r - FPC(v,b)$ denotes an r-frameproof code $\Gamma \subseteq \{0,1\}^v$ such that $|\Gamma| = b$. The codewords in the set $\Gamma$are called registered codewords. Therefore, if we have an r-frameproof code, then the pirate in the set C couldn't produce a registered illegal codeword other than their marks; that is not appropriate for the pirate copy. For more details about frameproof codes; see [1, 2, 11, 13, 14]. The following theorem was proved by Stinson, Trung, and Wei [10].

Theorem 1 [10] *Suppose Γ is an $r - FPC(v,b)$ with $b > 2r-1$. Suppose $D \subseteq \Gamma$, where $|D| = 2r-1$. Then there exists an unregistered word, say $maj(D) \in \{0,1\}^v$, such that $maj(D) \in F(C)$ for any $C \subseteq D$ with $|C| = r$.*

In view of the aforementioned theorem, $maj(D)$ is a codeword that is produced by the coalition of every r-subset of the set D. Therefore, in an $r - FPC$, there exist some illegal marks such that it is not possible to identify a pirate user. So they considered another condition and defined *secure frameproof codes* in which distributor is able to identify at least one pirate of the guilty coalitions.

Definition 2 *Suppose that Γ is a (v,t)-code. Γ is said to be an r-secure frameproof code if for any $C_1, C_2 \subseteq \Gamma$ with $|C_1| \leq r$, $|C_2| \leq r$, and $C_1 \cap C_2 = \varnothing$, we have $F(C_1) \cap F(C_2) = \varnothing$. Also, Γ is termed an $r - \mathrm{SFPC}(v,t)$, for short.*

In fact, when an illegal mark can be produced by two different r-subsets, in an $r - SFPC$, there exists at least one user in their intersection; whose can be considered as a pirate user. Stinson and Wei in [10] studied the relationship between binary secure frameproof codes and combinatorial aspects. In this paper, we establish the relationship between this concept and biclique cover. By a *biclique* we mean a bipartite graph with vertex set (X,Y) such that every vertex in X is adjacent to every vertex in Y. Note that every empty graph is a biclique. A *d-biclique cover* of a graph G of size s is a collection of s bicliques of G such that each edge of G is in at least d of the bicliques. The *d-biclique covering number* of G, denoted by $bc_d(G)$, is defined to be the minimum number of s such that there exists a d-biclique cover of size s for the graph G. For abbreviation, let $bc(G)$ stand for $bc_1(G)$.

Definition 3 *Let X be an n-set and $\mathcal{F} = \{B_1, \ldots, B_t\}$ be a family of subsets of X. $\mathcal{F}$ is called an $(r,w;d)$-cover-free family if for any two subsets I, $J \subseteq [t]$ such that $|I| = r$, $|J| = w$, and $I \cap J = \varnothing$, the following condition holds*

$$|(\bigcap_{i \in I} B_i) \setminus (\bigcup_{j \in J} B_j)| \geq d.$$

We denote it briefly by $(r, w; d) - CFF(n, t)$.

The minimum number of elements of X for which there exists an $(r, w; d) - CFF$ with t members is denoted by $N((r, w; d), t)$. For convenience, we use the notation $N((r, w), t)$ instead of $N((r, w; 1), t)$. This parameter has been studied extensively in the literature; see [4, 5, 7, 12]. The incidence matrix of an $(r, w; d) - CFF$ is a $t \times n$ binary matrix A such that $a_{ij} = 1$ whenever $j \in B_i$ and $a_{ij} = 0$ otherwise. As usual, we denote by $[t]$ the set $\{1, 2, \ldots, t\}$, and denote by $\binom{[t]}{r}$ the collection of all r-subsets of$[t]$. The graph $I_t(r, w)$ is a bipartite graph with the vertex set $(\binom{[t]}{w}, \binom{[t]}{r})$ for which a w-subset is adjacent to an r-subset whenever their intersection is empty.

Theorem 2 [5] *For any positive integers r, w, d, and t, where* $t \geq r + w$, *we have*

$$N((r, w; d), t) = bc_d(I_t(r, w)).$$

Throughout this paper, we only consider finite simple graphs. For a graph G, let $V(G)$ and $E(G)$ denote its vertex and edge sets, respectively. The *Kneser graph* $\mathrm{KG}(t, r)$ is the graph with vertex set $\binom{[t]}{r}$, and A is adjacent to B if $A \cap B = \varnothing$. A *homomorphism* from G to H is a map $\phi : V(G) \longrightarrow V(H)$ such that adjacent vertices in G are mapped into adjacent vertices in H, i.e., $uv \in E(G)$ implies $\phi(u)\phi(v) \in E(H)$. In addition, if any edge in H is the image of some edge in$G$, then ϕ is termed an onto-edge homomorphism. In this paper, by A^c we mean the complement of the set A. In Section 2, we show that for $t \geq 2r$, an r-secure frameproof code of size t and length v exists if and only if there exists a 1-biclique cover of size v for the Kneser graph $\mathrm{KG}(t, r)$. Also, we wish to investigate some connection between the d-biclique covering number of Kneser graphs and cover-free families. Moreover, we present an upper bound for the biclique covering number of Kneser graphs. In Section 3, we will look more closely at the biclique covering number of Kneser graphs. Also, it is shown that if there exists a Hadamard matrix of order $4d$, then $N((1, 1; d), 8d - 2) = 4d$ and $bc_{2d}(K_{8d}) = 4d$.

2 Secure Frameproof Codes

For a subset A_i of $[t]$, the *indicator vector* of A_i is the vector $v_{A_i} = (v_1, \ldots, v_t)$, where $v_j = 1$ if $j \in A_i$ and $v_j = 0$ otherwise.

Theorem 3 *Let r, t, and v be positive integers, where* $t \geq 2r$. *An* $r - \mathrm{SFPC}(v, t)$ *exists if and only if there exists a biclique cover of size v for the Kneser graph* $\mathrm{KG}(t, r)$.

Proof: Assume that A is the incidence matrix of an $r - \mathrm{SFPC}(v, t)$. Assign to the jth column of A, the set A_j as follows

$$A_j \stackrel{\text{def}}{=} \{i |\ 1 \leq i \leq t, a_{ij} = 1\}.$$

Now, for $1 \leq j \leq v$, construct the bicliques G_j with vertex set (X_j, Y_j), where the vertices ofX_j are all r-subsets of A_j and the vertices of Y_j are all r-subsets of A_j^c, i.e., $[t] \setminus A_j$. It is easily seen that G_j, for $1 \leq j \leq v$, is a complete bipartite graph of $\mathrm{KG}(t, r)$. Let C_1C_2 be an arbitrary edge of $\mathrm{KG}(t, r)$. So $C_1, C_2 \subseteq [t]$, and $C_1 \cap C_2 = \varnothing$. Since A is the incidence matrix of an $r - \mathrm{SFPC}(v, t)$, we have $F(C_1) \cap F(C_2) = \varnothing$. This means that there exists a bit position i such that the ith bit of all code words of C_1 is c_i, for some $c_i \in \{0, 1\}$, and also the ith bit of all codewords of C_2 is $c_i + 1 \pmod 2$. So there exists a column of A such that all entries corresponding to the rows of C_1 are equal to 1 and all entries corresponding to the rows ofC_2 are equal to 0, or vice versa. Hence, $C_1C_2 \in E(G_i)$. Conversely, assume

that we have a biclique cover of size v for the graph $\mathrm{KG}(t,r)$. Our objective is to construct an r-SFPC. Label graphs in this biclique cover with $G_1,\ldots,G_v$, where G_i has as its vertex set (X_i,Y_i). Let A_i be the union of sets that lie in X_i. Consider the indicator vectors of A_i's , for $1\leq i\leq v$, and construct the matrix A whose columns are these vectors. Assume that C_1 and C_2 are two disjoint subsets of $[t]$ of size r, i.e., $C_1C_2\in E(\mathrm{KG}(t,r))$. Let G_i be the complete bipartite graph that covers the edge C_1C_2. Then in the ith column of the matrix A all entries corresponding to the rows of C_1 are equal to 1 and all entries corresponding to the rows of C_2 are equal to 0, or vice versa. Consequently, $F(C_1)\cap F(C_2)=\varnothing$. □

A *covering* of a graph G is a subset K of $V(G)$ such that every edge of G has at least one end in K. The number of vertices in a minimum covering of G is called the *covering number* of G and denoted by$\beta(G)$. In [10], Stinson, Trung, and Wei construct an$r-\mathrm{SFPC}(2\binom{2r-1}{r-1},2r+1)$.

Corollary 1 [10] *For any integer $r\geq 0$, there exists an $r-\mathrm{SFPC}(2\binom{2r-1}{r-1},2r+1)$.*

Proof: Easily, one can check that the biclique covering number of a graph G without C_4 as a subgraph is equal to the covering number of G. On the other hand, $\mathrm{KG}(2r+1,r)$ does not contain C_4 as a subgraph. So $bc(\mathrm{KG}(2r+1,r)))=\beta(\mathrm{KG}(2r+1,r))$. Also, it is a well-known fact that $\beta(\mathrm{KG}(t,r))=\frac{t-r}{r}\binom{t-1}{r-1}$. An easy computation confirms the assertion. □

In the next theorem, we show the relationship between the d-biclique cover of Kneser graphs and cover-free families.

Theorem 4 *For any positive integers r, d, and t, where $t\geq 2r$, it holds that*

$$bc_{2d}(\mathrm{KG}(t,r))\leq N((r,r;d),t)\leq 2bc_d(\mathrm{KG}(t,r)).$$

Proof: First, assume that we have an optimal $(r,r;d)-CFF(n,t)$, i.e., $n=N((r,r;d),t)$ with incidence matrix A. Assign to the jth column of A, the set A_j as follows

$$A_j\stackrel{\mathrm{def}}{=}\{i|\ 1\leq i\leq t,\ \ a_{ij}=1\}.$$

Consider the biclique G_j with vertex set (X_j,Y_j), where the vertices of X_j are all r-subsets of A_j and the vertices of Y_j are all r-subsets of A_j^c. Also, two vertices are adjacent if the subsets corresponding to these vertices are disjoint. It is not difficult to see that G_j's, for $1\leq j\leq N((r,r;d),t)$, form a $2d$-biclique cover of $\mathrm{KG}(t,r)$. So $bc_{2d}(\mathrm{KG}(t,r))\leq N((r,r;d),t)$.
Conversely, assume that we have a d-biclique cover of $\mathrm{KG}(t,r)$. Label graphs in this biclique cover with $G_1,\ldots,G_l$, where G_i has as its vertex set (X_i,Y_i). Let A_i be the union of sets that lie in X_i and B_i be the union of sets that lie in Y_i. Obviously, A_i and B_i are disjoint. Consider the indicator vectors of A_i's and B_i's, for $i=1,\ldots,l$. Construct the matrix A whose columns are these vectors. Then A is the incidence matrix of an $(r,r;d)-CFF(2l,t)$. So $N((r,r;d),t)\leq 2bc_d(\mathrm{KG}(t,r))$. □

Corollary 2 *For any positive integers r, and t, where $t\geq 2r$, it holds that*

$$bc_2(\mathrm{KG}(t,r))\leq N((r,r),t)\leq 2bc(\mathrm{KG}(t,r)).$$

A similar result has been obtained by Stinson et al. [10].

Theorem 5 [10] *Let r and t be positive integers, where $t\geq 2r$, then*

1. *If there exists an $r-SFPC(v,t)$, then there exists an $(r,r)-CFF(2v,t)$.*

2. *Any (r, r)-cover free family is an r-secure frameproof code.*

Stinson et al. [10] have obtained the following upper bounds for $SFPC$.

Theorem 6 [10] *Suppose that r and t are positive integers and $p = 1 - \frac{1}{2^{2r-1}}$. If*

$$v \geq \frac{\ln(\frac{1}{2}\binom{t}{r}\binom{t-r}{r})}{-\ln p},$$

then there exists an $r - SFPC(v, t)$.

The following upper bound is shown in Deng et al. [3], by the Lovász Local Lemma.

Theorem 7 [3] *There exists an $r - SFPC(v, t)$ if*

$$v \geq \frac{\ln(e(\binom{t}{r}\binom{t-r}{r}-\binom{t-2r}{r}\binom{t-3r}{r})))}{-\ln p},$$

where

$$p = 1 - \frac{1}{2^{2r-1}}.$$

Let $p = 1 - \frac{1}{2^{2r-1}}$. Using the approximation $e^{-x} \approx 1 - x$, if we set $x = \frac{1}{2^{2r-1}}$, then we can see that

$$\frac{1}{-\ln p} \approx 2^{2r-1}.$$

In the next theorem, by the alternation method, we present a bound that is a slight improvement of Theorem 6. Also, it is a slight improvement of Theorem 7 provided that t is not large relative to r.

Theorem 8 *Let r and t be positive integers. If $t > 3r$ and*

$$v \geq 2^{2r-1}(1 + \ln(\binom{\lceil \frac{t}{2} \rceil}{r}\binom{\lfloor \frac{t}{2} \rfloor}{r}))) \prod_{i=0}^{r-1}(1 - \frac{1}{t-2i+1}),$$

then there exists an $r - SFPC(v, t)$.

Proof: We show that if $v \geq \lfloor 2^{2r-1}(1 + \ln(\binom{\lceil \frac{t}{2} \rceil}{r}\binom{\lfloor \frac{t}{2} \rfloor}{r}))) \prod_{i=0}^{r-1}(1 - \frac{1}{t-2i+1})\rfloor$, then there exists a biclique cover of size v for the Kneser graph $\mathrm{KG}(t, r)$. Let $\mathcal{A}$ be $\binom{[t]}{\lceil \frac{t}{2} \rceil}$. For every member of $\mathcal{A}$, say A_i, we can construct the biclique G_i with vertex set (X_i, Y_i), where the vertices of X_i are all r-subsets of A_i and the vertices of Y_i are all r-subsets of A_i^c. We define $\mathcal{B}$ to be the collection of these bicliques. Let $p \in [0, 1]$ be arbitrary, later, we specify an optimized value for p. Let us pick, randomly and independently, each biclique of $\mathcal{B}$ with probability p and $\mathcal{F}$ be the random set of all bicliques picked and let $Y_{\mathcal{F}}$ be the set of all edges AB of the graph $\mathrm{KG}(t, r)$ which are not covered by the set $\mathcal{F}$. The expected value of $|\mathcal{F}|$ is clearly $\binom{t}{\lceil \frac{t}{2} \rceil}p$. For every edge AB, $pr(AB \in Y_{\mathcal{F}}) = (1-p)^l$ where $l = 2\binom{t-2r}{\lceil \frac{t}{2} \rceil - r}$. So the expected value of the $|\mathcal{F}| + |Y_{\mathcal{F}}|$ is at most

$$\binom{t}{\lceil \frac{t}{2} \rceil}p + \frac{1}{2}\binom{t}{r}\binom{t-r}{r}(1-p)^{2\binom{t-2r}{\lceil \frac{t}{2} \rceil - r}}.$$

If we set $\mathcal{F}' = \mathcal{F} \bigcup Y_{\mathcal{F}}$, then clearly all edges of the graph $\mathrm{KG}(t, r)$ are covered by $\mathcal{F}'$. So we want to estimate p such that $|\mathcal{F}'|$ is minimum. For convenient, we bound $1 - p \leq e^{-p}$ to obtain

$$E(|\mathcal{F}| + |Y_{\mathcal{F}}|) \leq \binom{t}{\lceil \frac{t}{2} \rceil}p + \frac{1}{2}\binom{t}{r}\binom{t-r}{r}e^{-2\binom{t-2r}{\lceil \frac{t}{2} \rceil - r}p}.$$

The right hand side is minimized at $p = \frac{\ln \alpha}{\beta}$, which $\alpha = \binom{\lceil \frac{t}{2} \rceil}{r}\binom{\lfloor \frac{t}{2} \rfloor}{r}$ and $\beta = 2\binom{t-2r}{\lceil \frac{t}{2} \rceil - r}$ where $p \in [0, 1]$ if t is sufficiently large respect to r (e.g., $t > 3r$). So we have an $r - SFPC(v, t)$ that

$$v \leq \frac{\binom{t}{\lceil \frac{t}{2} \rceil}}{2\binom{t-2r}{\lceil \frac{t}{2} \rceil - r}}(1 + \ln(\binom{\lceil \frac{t}{2} \rceil}{r}\binom{\lfloor \frac{t}{2} \rfloor}{r})).$$

Furthermore, it is straightforward to check that

$$\frac{\binom{t}{\lceil \frac{t}{2} \rceil}}{2\binom{t-2r}{\lceil \frac{t}{2} \rceil - r}} \leq 2^{2r-1}\prod_{i=0}^{r-1}(1 - \frac{1}{t-2i+1}).$$

Hence, the bound follows. □

3 Biclique Cover of Kneser Graphs

By the mentioned results in the previous section, it may be of interest to find some bounds for the biclique covering number of Kneser graphs.

Theorem 9 *For any positive integers d, r, s, and t, where $t > 2r$ and $r > s$, we have*

$$bc_d(\mathrm{KG}(t,r)) \geq bc_m(\mathrm{KG}(t,s)),$$

where $m = N((r-s, r-s; d), t-2s)$.

Proof: Let $\{G_1, G_2, \ldots, G_l\}$ be an optimal d-biclique cover of $\mathrm{KG}(t,r)$. Also, assume that G_i has as its vertex set (X_i, Y_i). Let A_i and B_i be the union of sets that lie in X_i and Y_i, respectively. For any $1 \leq i \leq l$, consider the biclique G'_i, as a subgraph of $\mathrm{KG}(t,s)$, with vertex set (X'_i, Y'_i), where X'_i is the set of all s-subsets of A_i and Y'_i is the set of all s-subsets of B_i. One can check thatG'_i's cover all edges of $\mathrm{KG}(t,s)$. Moreover, any edge $UV \in E(\mathrm{KG}(t,s))$ is contained in at least m-bicliques, where $m = N((r-s, r-s; d), t-2s)$. To see this, consider the bipartite graph $I_{\{U,V\}}$ (as an induced subgraph of $\mathrm{KG}(t,r)$) with vertex set (X_U, Y_V), where

$$X_U = \{W |\ U \subseteq W \subseteq [t], W \cap V = \emptyset, |W| = r\}$$
$$Y_V = \{W |\ V \subseteq W \subseteq [t], W \cap U = \emptyset, |W| = r\}.$$

It is a simple matter to check that $I_{\{U,V\}}$ and $I_{t-2s}(r-s, r-s)$ are isomorphic. Also, if G_j covers any edge of $I_{\{U,V\}}$, then UV is contained in G'_j. Consequently, by Theorem 2 the assertion follows. □

In view of the proof of Theorem 9, similarly, one can extend any biclique of $I_t(r,w)$ to a biclique of $I_t(r-i, w-j)$. Consequently, we have the following theorem.

Theorem 10 *Let d, r, w, and t be positive integers, where $t \geq r + w$. For any $1 \leq i < r$ and $1 \leq j < w$, we have $N((r,w;d),t) \geq N((r-i, w-j; m), t)$, where $m = N((i,j;d), t-r-w+i+j)$.*

The fractional biclique covering number $bc^*(G)$ is defined as follows

$$bc^*(G) = \inf_d \frac{bc_d(G)}{d} = \lim_{d\to\infty} \frac{bc_d(G)}{d}.$$

It is known that if a graph is edge-transitive, then one can compute its fractional biclique covering number, see [9] for more about fractional graph theory.

Theorem 11 [9] *For every non-empty edge-transitive graph G,*

$$bc^*(G) = \frac{|E(G)|}{B(G)},$$

where $B(G)$ is the maximum number of edges among the bicliques of G.

The next result is a consequence of Theorem 10.

Theorem 12 [12] *Let d, r, w, i, j, and t be non-negative integers, where $t \geq r + w$, $1 \leq i < r$, and $1 \leq j < w$. Then*

$$N((r, w; d), t) \geq N((i, j; d), t - r - w + i + j) \min_{w-j \leq m \leq t-r+i} \frac{\binom{t}{m}}{\binom{t-r-w+i+j}{m-w+j}}.$$

Proof: In view of definition of fractional biclique cover and since $bc_{ts}(G) \leq s.bc_t(G)$ for every positive integers t and s, one can conclude that for every graph G, we have $t.bc^*(G) \leq bc_t(G)$. By this fact and using Theorem 10, we have

$$N((r, w; d), t) \geq N((i, j; d), t - r - w + i + j) bc^*(I_t(r - i, w - j)). \tag{1}$$

The graph $I_t(r, w)$ is an edge-transitive graph. Therefore, using Theorem 11 and an easy calculation

$$bc^*(I_t(r, w)) = \min_{t'+t''=t} \frac{\binom{t}{r}\binom{t-r}{w}}{\binom{t'}{r}\binom{t''}{w}} = \min_{w \leq m \leq t-r} \frac{\binom{t}{m}}{\binom{t-r-w}{m-w}}.$$

Therefore, according to the inequality 1 it follows that

$$N((r, w; d), t) \geq N((i, j; d), t - r - w + i + j) \min_{w-j \leq m \leq t-r+i} \frac{\binom{t}{m}}{\binom{t-r-w+i+j}{m-w+j}}.$$

□

We know that the image of a biclique under a graph homomorphism is a biclique. This leads us to the following lemma.

Lemma 1 *Let G and H be two graphs and $\phi : G \to H$ be an onto-edge homomorphism. Also, assume that d and t are positive integers and for any edge $e \in E(H)$, $bc_d(\phi^{-1}(e)) \geq t$. Then $bc_d(G) \geq bc_t(H)$.*

Proof: Let $\{K_1, K_2, \ldots, K_l\}$ be an optimal d-biclique cover of G. One can check that for any $0 \leq i \leq l$, $\phi(K_i)$ is a biclique and the family $\{\phi(K_1), \phi(K_2), \ldots, \phi(K_l)\}$ is a t-biclique cover of H. □

Proposition 1 *For any positive integers t and r, where $t > 2r$, we have*

$$bc_d(\mathrm{KG}(t, r)) \geq bc_{3d}(\mathrm{KG}(t - 2, r - 1)).$$

Proof: First, we present an onto-edge homomorphism ϕ from $\mathrm{KG}(t, r)$ to $\mathrm{KG}(t - 2, r - 1)$. To see this, for every vertex A of $\mathrm{KG}(t, r)$, define $\phi(A) := A'$ as follows. If A does not contain both t and $t - 1$, then define $A' := A \setminus \{maxA\}$. Otherwise, set $A' := \{x\} \cup A \setminus \{t, t - 1\}$, where x is the maximum element of $[t - 2]$ absent from A. It is simple to check that the subgraph induced by the inverse image of any edge of $\mathrm{KG}(t - 2, r - 1)$ contains an induced cycle of size six or an induced matching of size three. Hence, in view of Lemma 1, if $\{K_1, \ldots, K_l\}$ is a d-biclique cover of $\mathrm{KG}(t, r)$, then $\{\phi(K_1), \ldots, \phi(K_l)\}$ is a $3d$-biclique cover of $\mathrm{KG}(t - 2, r - 1)$. □

The aforementioned results motivate us to consider the following question.

Question 1 *Let d, r, and t be positive integers, where $t > 2r$. What is the exact value of $bc_d(\mathrm{KG}(t, r))$?*

Determining the exact value of the parameter $N((r, w; d), t)$, even for special r, w, d and t, is an interesting and challenging problem that is studied in the literature; see [5, 6, 7, 8]. An $n \times n$ matrix H with entries $+1$ and -1 is called a *Hadamard matrix* of *order* n whenever $HH^t = nI$. It is not difficult to see that any two columns of H are also orthogonal. If we permute rows or columns or if we multiply some rows or columns by -1, then this property does not change. Two such Hadamard matrices are called *equivalent*. For a given Hadamard matrix, we can find an equivalent one for which the first row and the first column consist entirely of $+1$ï¿½s. Such a Hadamard matrix is called *normalized*. We will denote by $K^-_{m,m}$ the complete bipartite graph with a perfect matching removed. Obviously, $K^-_{m,m}$ is isomorphic to $I_m(1, 1)$.

Theorem 13 *Let d be a positive integer such that there exists a Hadamard matrix of order $4d$, then*

1. $bc_{2d}(K_{8d}) = 4d$,

2. $N((1, 1; d), 8d - 2) = bc_d(K^-_{8d-2,8d-2}) = 4d$.

Proof: Let $H = [h_{ij}]$ be a Hadamard matrix of order $4d$. Suppose that K_{8d} has $\{u_1, \ldots, u_{4d}, v_1, \ldots, v_{4d}\}$ as its vertex set. For the jth column of H, two sets X_j and Y_j are defined as follows

$$X_j := \{u_i | h_{ij} = +1\} \cup \{v_i | h_{ij} = -1\} \ \ \& \ \ Y_j := \{u_i | h_{ij} = -1\} \cup \{v_i | h_{ij} = +1\}.$$

By constructing a bipartite graph G_j with vertex set (X_j, Y_j), indeed, we assign a biclique to each column. It is well-known that for any two rows of a Hadamard matrix, the number of columns for which corresponding entries in these rows are different in sign, are equal to $2d$. So, for $i \neq j$ the edges u_iu_j, v_iv_j, and u_iv_j of the graph K_{8d} are covered by $2d$ bicliques. Also, for the edge u_iv_i, there exist $4d$ bicliques that cover it. According to the above argument every edge is covered at least $2d$ times, so $bc_{2d}(K_{8d}) \leq 4d$. On the other hand, for every graph G, we have $\frac{|E(G)|}{B(G)} \leq \frac{bc_d(G)}{d}$, where $B(G)$ is the maximum number of edges among the bicliques of G. Therefore,

$$4d - \tfrac{1}{2} \leq bc_{2d}(K_{8d}).$$

Since $bc_{2d}(K_{8d})$ is an integer, we have $4d \leq bc_{2d}(K_{8d})$ which completes the proof. For the proof of the second part, assume that H is a normalized Hadamard matrix of order $4d$. Delete the first row of H and denote it by $H' = [h'_{ij}]$. Also, assume that $K^-_{8d-2,8d-2}$ has (X, Y) as its vertex set where $X = \{u_1, \ldots, u_{4d-1}, v_1, \ldots, v_{4d-1}\}$, $Y = \{u'_1, \ldots, u'_{4d-1}, v'_1, \ldots, v'_{4d-1}\}$, and $u_iu'_i, v_iv'_i \notin E(K^-_{8d-2,8d-2})$. Assign to the jth column of H', two sets X_j and Y_j as follows

$$X_j := \{u_i | h'_{ij} = +1\} \cup \{v_i | h'_{ij} = -1\} \quad \& \quad Y_j := \{u'_i | h'_{ij} = -1\} \cup \{v'_i | h'_{ij} = +1\}.$$

By the same argument in the first part of the proof and using the well-known fact that in H' every two distinct rows i, j and for any $a, b \in \{-1, +1\}$ there are exactly $d$columns that the corresponding entries are a and b in the rows i and j, respectively, one can see that every edge is covered at least d times. So $bc_d(K^-_{8d-2,8d-2}) \leq 4d$. On the other hand, $4d - \frac{2d}{4d-1} \leq bc_d(K^-_{8d-2,8d-2})$, and $\frac{2d}{4d-1} < 1$. Therefore, $4d \leq bc_d(K^-_{8d-2,8d-2})$ which establishes the second part. □
