HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

7.5 ■ High-Resolution Satellite Imaging

Paula Craciun, INRIA
Josiane Zerubia, INRIA

Do you know that over 50 satellites are launched every year to orbit the Earth? Have you ever wondered what the purpose of these satellites is? Here is one of them.

With the launch of the first satellite, a new way of gathering information about the Earth's surface emerged. Highly sophisticated cameras are built on the satellites to obtain very high resolution images. Satellites nowadays provide images at a resolution of 0.3 meters, which means that you can even identify your own scooter! Huge amounts of data are collected every day using these cameras. Still, all this data is meaningless, unless the images are further analyzed and understood.

A first step in understanding what is represented in an image is to identify the objects which it contains. We will focus here on identifying boats in a harbor. Boat extraction in harbors is a preliminary step in obtaining more complex information from images such as traffic flow within the harbor, unusual events, etc.

When you look at a satellite image of a harbor, you can visually detect the boats based on their characteristics, such as the fact that they are usually in water, their white color, or their elliptical shape. All these characteristics make it easy for us humans to correctly identify the boats and discriminate them from other objects such as cars, buildings, or trees. Humans know the concept of a boat, but computers don't. Tell a computer to identify a boat, and it won't know what you're talking about.

In order to use a computer to detect boats, one must first identify all the characteristics that make a boat unique. Some of them were mentioned before; can you think of others? Once you write down a list of all such characteristics, you then have to define them in a mathematical manner. Put all these mathematical characteristics together and you have developed a mathematical model for boats in harbors. Keep in mind that you must model the boat itself, as well as the relationships between the boats. One example of a relationship between two boats is the fact that they are usually not allowed to overlap. Note that if the final result is not satisfying, it probably means that the model is poor, and you should try to improve it.

The last step is to integrate this model into a framework that allows you to extract only those objects that fit the model and neglect all others. Probabilities play an important role in this step. The computer will search for a configuration of objects until it finds the one that best describes the real data in the image. In the best case scenario you'll end up with a configuration that incorporates all the boats in the harbor. At that point, you can move on to do more interesting stuff with this information.
