Abstract. Statistic was done for the precipitation and evaporation monitoring data of Yuncheng from 1971 to 2007. The first-order seasonal autoregressive models were set up, considering separately for the normal and skewed distribution of rainfall and evaporation. Long series of monthly precipitation and evaporation sequences were generated. Compared the average, standard deviation and other parameters of simulation sequences with measured sequence, the results of skewed simulation had better agreement with the measured one. Then it proved that skewness model maintains the main statistical characteristics of the measured sequence. 20 groups of equal length with the measured sequence of precipitation and evaporation sequence could be generated through the skewness model. The sequence of irrigation water of the winter wheat multiple corns planting type had been calculated, using the " α " value method. And comparative analysis with the measured result was performed. The simulation computed result was found in good coincidence with the measure computed result.

Keywords: precipitation, evaporation, seasonal autoregressive model, irrigation water

1 Introduction

Crop irrigation water can be determined by the field water balance method, using the precipitation and evaporation data. Based on the long series of data, the scale of irrigation projects can be determined. Thus many of the data needed, actually the measured data were limited. Aiming at the randomness of precipitation and evaporation, the precipitation and evaporation were randomly treated, and simulated using random hydrology methods. Then Long series of irrigation water sequence can be calculated in order to develop irrigation schemes more in line with actual crop water demand. Azhar^[1] considered evapotranspiration, precipitation randomness, introduced a minimum of irrigation water requirement of rice cumulative probability distribution, and used to guide irrigated rice irrigation. Huan-Jie Cai^[2] simulated the daily precipitation and studied the irrigation problems of wheat and maize. Zuo Xiaoxia^[3] generated long series of precipitation and evaporation by the stochastic hydrology method. Then a long series of rice irrigation process were calculated using the cross-correlation of rainfall evaporation. Wen Ji^[4] simulated the evapotranspiration, and the results derived stochastic simulation model of winter wheat irrigation. Zai Song-mei^[5] simulated the precipitation and evapotranspiration using random hydrology methods based on time-series, and then the simulated values

were used into the water balance equation to determine the irrigation time and amount. Wen Ji ^[6] analyzed the stochastic simulation techniques of crop irrigation and pointed out that it has strong universality. This paper simulated the sequences of precipitation and evaporation by the seasonal autoregressive model, and calculated the sequence of crop irrigation water in Yuncheng.

2 Materials and Methods

2.1 Model

Seasonal autoregressive model is used to simulate monthly precipitation and evaporation. The general form of seasonal autoregressive model is as follows ^[7]:

$$z_{t,\tau} = \varphi_{1,\tau} z_{t,\tau-1} + \varphi_{2,\tau} z_{t,\tau-2} + \dots + \varphi_{p,\tau} z_{t,\tau-p} + \varepsilon_{t,\tau} \quad (1)$$

Where $Z_{t,\tau}$ is standardized sequence, $\varphi_{1,\tau}$ 、 $\varphi_{2,\tau}$ 、 \dots 、 $\varphi_{p,\tau}$ are respectively the autoregression coefficients of the τ season from 1 to p orders, and $\varepsilon_{t,\tau}$ is the independent random sequences of the t year of the τ season.

Standardized sequence which is to eliminate the seasonal effects of average、variance can be obtained by standardizing the hydrological series. Formula is as follows.

$$z_{t,\tau} = \frac{x_{t,\tau} - u_{\tau}}{\sigma_{\tau}} \quad (2)$$

Where u_{τ} is average, σ_{τ} is standard deviation, and $x_{t,\tau}$ is seasonal hydrological sequence($t=1,2, \dots, n$, n is the number of years; $\tau=1,2, \dots, w$, w is the number of seasons), which can be represented through matrix.

$$\begin{bmatrix} x_{1,1} & x_{1,2} & x_{1,3} & \dots & x_{1,w} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ x_{t,1} & x_{t,2} & x_{t,3} & \dots & x_{t,w} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ x_{n,1} & x_{n,2} & x_{n,3} & \dots & x_{n,w} \end{bmatrix} = \{x_{t,\tau}\}_{n \times w}$$

Studies show that a first or second order model will be able to meet the requirements. Thus this article uses a first order seasonal autoregressive model. When $p = 1$, the model is as follows.

$$z_{t,\tau} = \varphi_{1,\tau} z_{t,\tau-1} + \varepsilon_{t,\tau} \quad (3)$$

2.2 Estimation of Model's Parameters

Parameters of a first order seasonal autoregressive model are u_τ 、 σ_τ^2 、 $\varphi_{1,\tau}$ 、and $\sigma_{\varepsilon,\tau}^2$ ($\tau = 1, 2, \dots, w$) . Estimate of u_τ and σ_τ^2 can be separately reached with the average (\bar{x}_τ) and variance (s_τ^2) of the sample.

$$\hat{u}_\tau = \bar{x}_\tau = \frac{1}{n} \sum_{t=1}^n x_{t,\tau} \quad (4)$$

$$\hat{\sigma}_\tau^2 = s_\tau^2 = \frac{1}{n-1} \sum_{t=1}^n (x_{t,\tau} - \bar{x}_\tau)^2 \quad (5)$$

$$\varphi_{1,\tau} = \hat{\rho}_{1,\tau} = r_{1,\tau} = \frac{\sum_{t=1}^n (x_{t,\tau} - \bar{x}_\tau)(x_{t,\tau-1} - \bar{x}_{\tau-1})}{(n-1)s_\tau s_{\tau-1}} \quad (6)$$

Where $r_{1,\tau}$ is the τ season's first-order sample autocorrelation coefficient of the $x_{t,\tau}$ sequence, which indicates the linear correlation between the τ and $\tau-1$ season.

If the sequences of precipitation and evaporation are considered normal one, then the independent random sequence $\varepsilon_{t,\tau}$ is pure normal distribution. The formula is as follows.

$$\varepsilon_{t,\tau} = \sigma_{\varepsilon,\tau} \xi_{t,\tau} \quad (7)$$

$$\sigma_{\varepsilon,\tau} = \sqrt{1 - r_{1,\tau}^2} \quad (8)$$

$$\xi_\tau = \sqrt{-2 \ln u_{1,\tau}} \cos 2\pi u_{2,\tau} \quad (9)$$

Where $u_{1,\tau}$ and $u_{2,\tau}$ are uniformly distributed random numbers, and ξ_τ is the independent standard normal pure random sequence, namely $\xi_\tau \sim N(0,1)$. $\xi_{t,\tau}$ can be obtained by a lot of $u_{t,\tau}$.

If the sequences of precipitation and evaporation are considered skewed one, then the independent random sequence $\varepsilon_{t,\tau}$ is skewed distribution. In hydrology and water resources, the distribution of $\varepsilon_{t,\tau}$ more considers is a P-III type one. The formula is as follows.

$$\varepsilon_{t,\tau} = \sigma_{\varepsilon,\tau} \Phi_{t,\tau} \quad (10)$$

$$\Phi_{t,\tau} = \frac{2}{C_{S_{\Phi,\tau}}} \left(1 + \frac{C_{S_{\Phi,\tau}} \xi_{t,\tau}}{6} - \frac{C_{S_{\Phi,\tau}}^2}{36} \right)^3 - \frac{2}{C_{S_{\Phi,\tau}}} \quad (11)$$

$$C_{S_{\Phi,\tau}} = \frac{C_{S_{x,\tau}} - \varphi_{1,\tau}^3 C_{S_{x,\tau-1}}}{(1 - \varphi_{1,\tau} r_{1,\tau})^{3/2}} \quad (12)$$

$$C_{S_{x,\tau}} = \frac{1}{n-3} \frac{\sum_{t=1}^n (x_{t,\tau} - \bar{x}_\tau)^3}{s_\tau^3} \quad (13)$$

Where $\Phi_{t,\tau}$ is standardized P-III distributed random variable, $C_{S_{\Phi,\tau}}$ is coefficient of skewness of $\Phi_{t,\tau}$, and $C_{S_{x,\tau}}$ is coefficient of skewness of $x_{t,\tau}$.

2.3 Calculation of Irrigation Water

Irrigation water is the required amount of water of irrigated land, which is drawn from the source. It depends on the factors such as the irrigated area, crop cultivation, soils, hydrogeological and meteorological conditions. Farm irrigation water is calculated as follows:

$$M = \alpha E_0 - \beta P \quad (14)$$

Where M is crop irrigation water of the crops' whole growth period (mm), α is water demand coefficient, which determined by the measured data (see table 1), E_0 is water surface evaporation of the crops' whole growth period (mm), P is precipitation of the crops' whole growth period (mm), and β is effective utilization coefficient of precipitation, which determined by relevant information, the value of β is 0.9 in the months of 11,12,1-4, and in other months is 0.8.

Table 1. The value of α

month	1	2	3	4	5	6	7	8	9	10	11	12
α	0.4	0.552	0.665	0.722	0.74	0.743	0.75	0.83	0.73	0.397	0.593	0.462

3 Results and Discussion

3.1 Applicability Analysis of the Model

Statistic was done for the precipitation and evaporation monitoring data of Yuncheng from 1971 to 2007. Considering separately for the normal and skewed distribution of rainfall and evaporation, this paper set up the first-order seasonal autoregressive models. Then three groups of one hundred length sequences were generated. And thus this paper analyzed the parameters of model and application of model. The results were shown in Table 2 and Table 3.

Table 2. Results of model suitability testing of Yuncheng district's monthly precipitation

Table 2 and Table 3 showed that the average, standard deviation, coefficient of skewness and first autocorrelation coefficient of the skewness sequence all well maintained for the measured one. However the standard deviation and the first order autocorrelation coefficient could be maintained and the other parameters varied greatly for the measured sequences, such as the average of simulated precipitation in September deviated larger from the measured one (see Figure 1), and the coefficient of normal sequence deviated largest from the measured one (see Figure 2). The results showed that the normal and the measured precipitation sequences didn't come from the same total. But the parameters of normal evaporation sequence remain good, except the coefficient of skewness.

In addition, negative values were found in the simulated sequence of precipitation regardless of the normal or skewed distribution. It did not match the actual situation. Thus statistic was done for the sum of the negative number and negative value in three groups of 100 length simulated sequences. The results were shown in table 4. It also could be seen from table 3 that not only the number of negative in the skewness sequence was less than in the normal one, decreased by nearly 50%, but also the negative sum in the skewness sequence was much smaller than the normal one, decreased by nearly 90%. The result showed that precipitation sequence should be simulated by the skewness model.

Table 4. Statistics of the number and the negative sum of the negative in the simulated precipitation sequence

item	Simulation (normal)				Simulation (skewness)			
	sample1	sample2	sample3	average	sample1	sample2	sample3	average
Number of the negative	150	138	168	152	67	66	93	75
Sum of the negative	-2676.5	-2800.7	-2776.4	-2751.2	-274.9	-274.6	-439.1	-329.5

Figure 1. Comparison of the average of precipitation simulated and measured sequences

Figure 2. Comparison of the coefficient of skewness of precipitation simulated and measured sequences

3.2 Analysis of Irrigation Water's Frequency Curve

Through the skewness model, 20 groups of equal length with the measured sequence of precipitation and evaporation sequence can be generated. The sequence of irrigation water of the winter wheat multiple corns planting type had been calculated using the formula (12). Then based on the measured sequence of precipitation and evaporation, this paper calculated the measured irrigation water sequence using the " α " value method. Statistic was done for the data of irrigation water by frequency calculation method. Finally, five simulation groups of irrigation

water's frequency curves were compared with the measured one. The results were shown in figure 3.

Figure 3. The frequency curves of irrigation water

Figure 3 showed that simulated frequency curves fit the measured one good. 20 groups of equal length with the measured sequence of simulated irrigation water were compared with the measured one. The results were shown in table 5 and 6. As can be seen from table 5, the average, standard deviation and coefficient of skewness of simulated sequences well maintained for the measured one. Table 6 showed that the differences between simulated irrigation water sequences and measured one were little, and the difference between the maximum and minimum values was from 100 to 200 mm. If approximatively taking the average of 20 simulated groups as the average of total, the measured values of irrigation water were larger than the total's average between the 50% and 90% frequencies. Thus if the scale of irrigation projects was determined using the measured sequence, the result could be larger than the actual.

Table 5. Statistical parameters of irrigation water simulation sequences and measured values sequences

	\bar{x}	σ_r	C_s
measured	863.6	242.1	-0.333
simulation average	865.9	217.8	-0.306

Table 6. Comparison of measured and simulated values at different frequencies (mm)

frequency	measured	simulation	max	min	max-min
25%	670	717	810	636	174
50%	932	883	942	824	118
75%	1069	1027	1086	944	142
90%	1141	1134	1205	1036	169
95%	1224	1256	1315	1122	193

4 Conclusions

Precipitation and evaporation of Yuncheng were simulated by the seasonal autoregressive model, which considered separately for the normal and skewed distribution of precipitation and evaporation. Long series of monthly precipitation and evaporation sequences were generated. The simulation results showed that the skewed simulation had better agreement with the measured. Then based on the data of skewed distribution, this paper established the relations formula of water evaporation and crop water requirement, and calculated the crop water requirement. The long series of crop irrigation water were obtained through the water balance calculation. Comparing with the measured irrigation water, it verified the practicability of the model. The results showed that the model was feasible in allowable error.
