## Abstract

We consider non-linear regression problems where we assume that the response depends non-linearly on a linear projection of the covariates. We propose score function extensions to sliced inverse regression problems, both for the first- order and second-order score functions. We show that they provably improve estimation in the population case over the non-sliced versions and we study finite sample estimators and their consistency given the exact score functions. We also propose to learn the score function as well, in two steps, i.e., first learning the score function and then learning the effective dimension reduction space, or directly, by solving a convex optimization problem regularized by the nuclear norm. We illustrate our results on a series of experiments.

## 1 Introduction

Non-linear regression and related problems such as non-linear classification are core important tasks in machine learning and statistics. In this paper, we consider a random vector  $x \in \mathbb{R}^d$ , a random response  $y \in \mathbb{R}$ , and a regression model of the form

$$y = f(x) + \varepsilon, \tag{1.1}$$

which we want to estimate from  $n$  independent and identically distributed (i.i.d.) observations  $(x_i, y_i)$ ,  $i = 1, \dots, n$ . Our goal is to estimate the function  $f$  from these data. A traditional key difficulty in this general regression problem is the lack of parametric assumptions regarding the functional form of  $f$ , leading to a problem of *non-parametric* regression. This is often tackled by searching implicitly or explicitly a function  $f$  within an infinite-dimensional vector space.

While several techniques exist to estimate such a function, e.g., kernel methods, local-averaging, or neural networks (see, e.g., [13]), they also suffer from the *curse of dimensionality*, that is, the rate of convergence of the estimated function to the true function (with any relevant performance measure) can only decrease as a small power of  $n$ , and this power cannot be larger than a constant divided by  $d$ . In other words, the number  $n$  of observations for any level of precision is exponential in dimension.

A classical way of by-passing the curse of dimensionality is to make extra assumptions regarding the function to estimate, such as the dependence on a lower unknown low-dimensional subspace, such as done by projection pursuit or neural networks. More precisely, throughout the paper, we make the following assumption:

- (A1)** For all  $x \in \mathbb{R}^d$ , we have  $f(x) = g(w^\top x)$  for a certain matrix  $w \in \mathbb{R}^{d \times k}$  and a function  $g : \mathbb{R}^k \rightarrow \mathbb{R}$ . Moreover,  $y = f(x) + \varepsilon$  with  $\varepsilon$  independent of  $x$  with zero mean and finite variance.

The subspace of  $\mathbb{R}^d$  spanned by the  $k$  columns  $w_1, \dots, w_k \in \mathbb{R}^d$  of  $w$  has dimension less than or equal to  $k$ , and is often called the *effective dimension reduction* (e.d.r.) space. The model above is often referred to as a *multiple-index model* [28]. We will always make the assumption that the e.d.r. space has exactly rank  $k$ , that is the matrix  $w$  has rank  $k$  (which implies that  $k \leq d$ ).

Our goal is to estimate both the non-linear function  $g$  and the matrix  $w$ , with the hope of obtaining a convergence rate where the inverse power of  $n$  will now be proportional to  $k$  and not  $d$ . Note that the matrix  $w$  is only identifiable up to a (right) linear transform, since only the subspace spanned by its column is characteristic.

Given  $w$ , estimating  $g$  may be done by any technique in non-parametric regression, with a convergence rate which requires a number of observations  $n$  to be exponential in  $k$ . Given the non-linear function  $g$ , estimating  $w$  is computationally difficult because the resulting optimization problem may not be convex and thus leads to several local minima. Our difficulty is even stronger since we want to estimate *both* the function  $g$  and the matrix  $w$ .

In this paper, we consider a specific instantiation of the method of moments, which partially circumvents this difficulty by estimating  $w$  directly without the knowledge of  $g$ . The starting point for this method is the work by Brillinger [6], which shows, as a simple consequence of Stein’s lemma [23], that if the distribution of  $x$  is Gaussian, and **(A1)** is satisfied with  $k = 1$  (e.d.r. of dimension one, e.g., a single-index model), and the input data have zero mean and identity covariance matrix, then the expectation  $\mathbb{E}(yx)$  is proportional to  $w$ . Thus, a certain expectation, which can be easily approximated given i.i.d. observations, *simultaneously* eliminates  $g$  and reveals  $w$ .

While the result above provides a very simple algorithm to recover  $w$ , it has several strong limitations: (a) it only applies to normally distributed data  $x$ , or more generally to elliptically symmetric distributions [7], (b) it only applies to  $k = 1$ , and (c) in many situations with symmetries, the proportionality constant is equal to zero and thus we cannot recover the vector  $w$ . This has led to several extensions in the statistical literature which we now present.

**Using score functions.** The use of Stein’s lemma with a Gaussian random variable can be directly extended using the score function  $\mathcal{S}_1(x)$  defined as the negative gradient of the log-density, that is,  $\mathcal{S}_1(x) = -\nabla \log p(x) = \frac{1}{p(x)} \nabla p(x)$ , which leads to the following assumption:

- (A2)** The distribution of  $x$  has a strictly positive density  $p(x)$  which is differentiable with respect to the Lebesgue measure, and such that  $p(x) \rightarrow 0$  when  $\|x\| \rightarrow +\infty$ .

We will need the score to be sub-Gaussian to obtain consistency results. Given Assumption **(A2)**, then [25] showed, as a simple consequence of integration by parts, that, for  $k = 1$  and if Assumption **(A1)** is satisfied, then  $\mathbb{E}(y\mathcal{S}_1(x))$  is proportional to  $w$ , for all differentiable functions  $g$ , with a proportionality constant that depends on  $w$  and  $\nabla g$ . This leads to the “average derivative method” (ADE) and thus replaces the Gaussian assumption by the existence of a differentiable log-density, which is much weaker. This however does not remove the restriction  $k = 1$ , which can be done in two ways which we now present.

**Sliced inverse regression.** Given a normalized Gaussian distribution for  $x$  (or any elliptically symmetric distribution), then, if **(A1)** is satisfied, almost surely in  $y$ , the conditional expectation  $\mathbb{E}(x|y)$  happens to belong to the e.d.r. subspace. Given several distinct values of  $y$ , the vectors  $\mathbb{E}(x|y)$  or any estimate thereof, will hopefully span the entire e.d.r. space and we can recover the entire matrix  $w$ , leading to “slice inverse regression” (SIR), originally proposed by Li and Duan [21], Duan and Li [12] and Li [19]. This allows the estimation with  $k > 1$ , but this is still restricted to Gaussian data. In this paper, we propose to extend SIR by the use of score functions to go beyond elliptically symmetric distributions, and we show that the new method combining SIR and score functions is formally better than the plain ADE method.

**From first-order to second-order moments.** Another line of extension of the simple method of Brillinger [6] is to consider higher-order moments, namely the matrix  $\mathbb{E}(yxx^\top) \in \mathbb{R}^{d \times d}$ , which, with normally distributed input data  $x$  and if (A1) is satisfied, will be proportional (in a particular form to be described in Section 2.2) to the Hessian of the function  $g$ , leading to the method of “principal Hessian directions” (PHD) from Li [20]. Again,  $k > 1$  is allowed (more than a single projection), but thus is limited to elliptically symmetric data. Janzamin, Sedghi and Anandkumar [17] proposed to use second-order score functions to go beyond this assumption. In order to define this new method, we consider the following assumption:

- (A3) The distribution of  $x$  has a strictly positive density  $p(x)$  which is twice differentiable with respect to the Lebesgue measure, and such that  $p(x)$  and  $\|\nabla p(x)\| \rightarrow 0$  when  $\|x\| \rightarrow +\infty$ .

Given (A1) and (A3), then one can show [17] that  $\mathbb{E}(y\mathcal{S}_2(x))$  will be proportional to the Hessian of the function  $g$ , where  $\mathcal{S}_2(x) = \nabla^2 \log p(x) + \mathcal{S}_1(x)\mathcal{S}_1(x)^\top = \frac{1}{p(x)}\nabla^2 p(x)$ , thus extending the Gaussian situation above where  $\mathcal{S}_1$  was a linear function and  $\mathcal{S}_2(x)$ , up to linear terms, proportional to  $xx^\top$ .

In this paper, we propose to extend the method above to allow an SIR estimator for the second-order score functions, where we condition on  $y$ , and we show that the new method is formally better than the plain method of [17].

**Learning score functions through score matching.** Relying on score functions immediately raises the following question: is estimating the score function really simpler than our original problem of non-parametric regression? Fortunately, a recent line of work [1] has considered this exact problem, and formulated the task of density estimation directly on score functions, which is particularly useful in our context. We may then use the data, first to learn the score, and then to use the novel score-based moments to estimate  $w$ . We will also consider a direct approach that jointly estimates the score function and the e.d.r. subspace, by regularizing by a sparsity-inducing norm.

**Fighting the curse of dimensionality.** Learning the score function is still a non-parametric problem, with the associated curse of dimensionality. If we first learn the score function (through score matching) and then learn the matrix  $w$ , we will not escape that curse, while our direct approach is empirically more robust.

Note that Hristache, Juditsky and Spokoiny [15] suggested iterative improvements of the ADE method, using elliptic windows which shrink in the directions of the columns of  $w$ , stretch in all others directions and tend to flat layers orthogonal to  $w$ . Dalalyan, Juditsky and Spokoiny [11] generalize the algorithm to multi-index models and proved  $\sqrt{n}$ -consistency of the proposed procedure in the case when the structural dimension is not larger than 4 and weaker dependence for  $d > 4$ . In particular, they provably avoid the curse of dimensionality. Such extensions are outside the scope of this paper.

**Contributions.** In this paper, we make the following contributions:

- We propose score function extensions to sliced inverse regression problems, both for the first-order and second-order score functions. We consider the infinite sample case in Section 2 and the finite sample case in Section 3. They provably improve estimation in the population case over the non-sliced versions, while we study in Section 3 finite sample estimators and their consistency given the exact score functions.
- We propose in Section 4 to learn the score function as well, in two steps, i.e., first learning the score function and then learning the e.d.r. space parameterized by  $w$ , or directly, by solving a convex optimization problem regularized by the nuclear norm.
- We illustrate our results in Section 5 on a series of experiments.

## 2 Estimation with infinite sample size

In this section, we focus on the population situation, where we can compute expectations and conditional expectations exactly, while we focus on finite sample estimators with known score functions in Section 3 with consistency results in Section 3.3, and with learned score functions in Section 4.

### 2.1 SADE: Sliced average derivative estimation

Before presenting our new moments which will lead to the novel SADE method, we consider the non-sliced method, which is based on Assumptions **(A1)** and **(A2)** and score functions (the method based on the Gaussian assumption will be derived later as corollaries). The ADE method is based on the following lemma:

**Lemma 1** (ADE moment [25]). *Assume **(A1)** and **(A2)**. Then  $\mathbb{E}(\mathcal{S}_1(x)y)$  is in the e.d.r. subspace.*

*Proof.* Since  $y = f(x) + \varepsilon$ , and  $\varepsilon$  is independent of  $x$  with zero mean, we have

$$\begin{aligned} \mathbb{E}(\mathcal{S}_1(x)y) &= \mathbb{E}(\mathcal{S}_1(x)f(x)) = \int_{\mathbb{R}^d} \frac{-\nabla p(x)}{p(x)} f(x) p(x) dx \\ &= - \int_{\mathbb{R}^d} \nabla p(x) f(x) dx = \int_{\mathbb{R}^d} p(x) \nabla f(x) dx \text{ by integration by parts,} \\ &= w \cdot \mathbb{E}(g'(w^\top x)), \end{aligned}$$

which leads to the desired result. Note that in the integration by parts above, the decay of  $p(x)$  to zero for  $\|x\| \rightarrow +\infty$  is needed.  $\square$

The ADE moment above only provides a single vector in the e.d.r. subspace, which can only potentially lead to recovery for  $k = 1$ , and only if  $\mathbb{E}(g'(w^\top x)) \neq 0$ , which may not be satisfied, e.g., if  $x$  has a symmetric distribution and  $g$  is even.

We can now present our first new lemma, the proof of which relies on similar arguments as for SIR [21] but extended to score functions:

**Lemma 2** (SADE moment). *Assume **(A1)** and **(A2)**. Then,  $\mathbb{E}(\mathcal{S}_1(x)|y)$  is in the e.d.r. subspace almost surely (in  $y$ ).*

*Proof.* We consider any vector  $b \in \mathbb{R}^d$  in the orthogonal complement of  $\text{Span}\{w_1, \dots, w_k\}$ . We need to show, that  $b^\top \mathbb{E}(\mathcal{S}_1(x)|y) = 0$  with probability 1. We have by the law of total expectation

$$b^\top \mathbb{E}(\mathcal{S}_1(x)|y) = \mathbb{E}\left(\mathbb{E}(b^\top \mathcal{S}_1(x)|w_1^\top x, \dots, w_k^\top x, y)|y\right).$$

Because of Assumption **(A1)**, we have  $y = g(w^\top x) + \varepsilon$  with  $\varepsilon$  independent of  $x$ , and thus

$$\mathbb{E}(b^\top \mathcal{S}_1(x)|w^\top x, y) = \mathbb{E}(b^\top \mathcal{S}_1(x)|w^\top x, \varepsilon) = \mathbb{E}(b^\top \mathcal{S}_1(x)|w^\top x) \text{ almost surely.}$$

This leads to

$$b^\top \mathbb{E}(\mathcal{S}_1(x)|y) = \mathbb{E}[\mathbb{E}(b^\top \mathcal{S}_1(x)|w^\top x)|y].$$

We now prove that almost surely  $\mathbb{E}(b^\top \mathcal{S}_1(x)|w^\top x) = 0$ , which will be sufficient to prove Lemma 2.

We consider the linear transformation of coordinates:  $\tilde{x} = \tilde{w}^\top x \in \mathbb{R}^d$ , where  $\tilde{w} = (w_1, \dots, w_k, w_{k+1}, \dots, w_d)$  is a square matrix with full rank obtained by adding a basis of the subspace orthogonal to the span of the  $k$  columns of  $w$ . Then, if  $\tilde{p}$  is the density of  $\tilde{x}$ , we have  $p(x) = (\det \tilde{w}) \cdot \tilde{p}(\tilde{x})$  and thus  $\nabla p(x) = (\det \tilde{w}) \tilde{w} \cdot \nabla \tilde{p}(\tilde{x})$  and  $\tilde{b} = \tilde{w}^\top b = (0, \dots, 0, \tilde{b}_{k+1}, \dots, \tilde{b}_d) \in \mathbb{R}^d$  (because  $b \perp \text{Span}\{w_1, \dots, w_k\}$ );

moreover,  $\tilde{\mathcal{S}}_1(\tilde{x}) = \tilde{w}\mathcal{S}_1(x)$  (because the determinant term is cancelled), and the desired conditional expectation equals

$$\tilde{w} \cdot \mathbb{E}(\tilde{b}^\top \tilde{\mathcal{S}}_1(\tilde{x}) | \tilde{x}_1, \dots, \tilde{x}_k),$$

and  $\tilde{w}\tilde{\mathcal{S}}_1(\tilde{x}) = \frac{\tilde{w}\nabla\tilde{p}(\tilde{x})}{\tilde{p}(\tilde{x})} = \frac{\nabla p(x)}{p(x)} = \mathcal{S}_1(x)$  and hence  $b^\top \mathcal{S}_1(x) = b^\top \tilde{w} \tilde{\mathcal{S}}_1(\tilde{x}) = \tilde{b}^\top \tilde{\mathcal{S}}_1(\tilde{x})$ .

It is thus sufficient to show that  $\int_{\mathbb{R}^{d-k}} \tilde{b}^\top \tilde{\mathcal{S}}_1(\tilde{x}) \tilde{p}(\tilde{x}_1, \dots, \tilde{x}_d) d\tilde{x}_{k+1} \dots d\tilde{x}_d = 0$ , for all  $\tilde{x}_1, \dots, \tilde{x}_k$ .

We have

$$\begin{aligned} & \int_{\mathbb{R}^{d-k}} \tilde{b}^\top \tilde{\mathcal{S}}_1(\tilde{x}) \tilde{p}(\tilde{x}_1, \dots, \tilde{x}_d) d\tilde{x}_{k+1} \dots d\tilde{x}_d = \tilde{b}^\top \int_{\mathbb{R}^{d-k}} \nabla \tilde{p}(\tilde{x}) \cdot d\tilde{x}_{k+1} \dots d\tilde{x}_d \\ & = \sum_{j=k+1}^d \tilde{b}_j \cdot \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \dots \int_{-\infty}^{\infty} \frac{\partial \tilde{p}(\tilde{x})}{\partial \tilde{x}_j} d\tilde{x}_j \cdot \prod_{\substack{k+1 \leq t \leq d \\ t \neq j}} d\tilde{x}_t = 0, \end{aligned}$$

because for any  $j \in \{k+1, \dots, n\}$ ,  $\int_{-\infty}^{\infty} \frac{\partial \tilde{p}(\tilde{x})}{\partial \tilde{x}_j} d\tilde{x}_j = 0$  by Assumption **(A2)**. This leads to the desired result.  $\square$

The key difference is now that by conditioning on different values of  $y$ , we have access to *several* vectors  $\mathbb{E}(\mathcal{S}_1(x)|y) \in \mathbb{R}^d$ . In the population case, we will consider the following matrix

$$\mathcal{V}_1 = \mathbb{E}[\mathbb{E}(\mathcal{S}_1(x)|y)\mathbb{E}(\mathcal{S}_1(x)|y)^\top] \in \mathbb{R}^{d \times d},$$

which we will also denote  $\mathbb{E}[\mathbb{E}(\mathcal{S}_1(x)|y)^{\otimes 2}]$ , where for any matrix  $a$ ,  $a^{\otimes 2}$  denotes  $aa^\top$ . The matrix above is positive semi-definite, and its column space is included in the e.d.r. space. If it has rank  $k$ , then we can exactly recover the entire subspace by an eigenvalue decomposition. When  $k = 1$ , which is the only case where ADE may be used, the following proposition shows that if ADE allows to recover  $w$ , so is SADE.

We will also consider the other matrix (note the presence of the extra term  $y^2$ )

$$\mathcal{V}'_1 = \mathbb{E}[y^2 \mathbb{E}(\mathcal{S}_1(x)|y)\mathbb{E}(\mathcal{S}_1(x)|y)^\top],$$

because of its direct link with the non-sliced version.

**Proposition 1.** *Assume **(A1)** and **(A2)**, with  $k = 1$ . The vector  $w$  may be recovered from the ADE moment (up to scale) if and only if  $\mathbb{E}g'(w^\top x) \neq 0$ . If this condition is satisfied, then SADE also recovers  $w$  up to scale (i.e.,  $\mathcal{V}_1$  and  $\mathcal{V}'_1$  are different from zero).*

*Proof.* The first statement is a consequence of the proof of Lemma 1. If SADE fails, that is, for almost all  $y$ ,  $\mathbb{E}(\mathcal{S}_1(x)|y) = 0$ , then  $\mathbb{E}(\mathcal{S}_1(x)y|y) = 0$  which implies that  $\mathbb{E}(\mathcal{S}_1(x)y) = 0$  and thus ADE fails. Moreover, we have, using operator convexity [26]:

$$\begin{aligned} \mathcal{V}'_1 &= \mathbb{E}[\mathbb{E}(y\mathcal{S}_1(x)|y)\mathbb{E}(y\mathcal{S}_1(x)|y)^\top] \succcurlyeq [\mathbb{E}(\mathbb{E}(y\mathcal{S}_1(x)|y))][\mathbb{E}(\mathbb{E}(y\mathcal{S}_1(x)|y))]^\top = \\ &= [\mathbb{E}(y\mathcal{S}_1(x))][\mathbb{E}(y\mathcal{S}_1(x))]^\top, \end{aligned}$$

showing that the new moment is dominating the ADE moment, which provides an alternative proof of the rank of  $\mathcal{V}'_1$  being larger than one if  $\mathbb{E}(y\mathcal{S}_1(x)) \neq 0$ .  $\square$

**Elliptically symmetric distributions.** If  $x$  is normally distributed with mean vector  $\mu$  and covariance matrix  $\Sigma$ , then we have  $\mathcal{S}_1(x) = \Sigma^{-1}(x - \mu)$  and we recover the result from [21]. Note that the lemma then extends to all elliptical distributions of the form  $\varphi(\frac{1}{2}(x - \mu)^\top \Sigma^{-1}(x - \mu))$ , for a certain function  $\varphi : \mathbb{R}^+ \rightarrow \mathbb{R}$ . See [21].

**Failure modes.** In some cases, slice inverse regression does not span the entire e.d.r. space, because the inverse regression curve  $\mathbb{E}(\mathcal{S}_1(x)|y)$  is degenerated. For example, this can occur, if  $k = 1$ ,  $y = h(w_1^\top x) + \varepsilon$ ,  $h$  is an even function and  $w_1^\top x$  has a symmetric distribution around 0. Then  $\mathbb{E}(\mathcal{S}_1(x)|y) \equiv 0$ , and thus it is a poor estimation of the desired e.d.r. directions [10].

The second drawback of SIR occurs when we have a classification task, for example,  $y \in \{0, 1\}$ . In this case, we have only two slices (i.e., possible values of  $y$ ) and SIR can recover only one direction in the e.d.r. space [9].

Li [20] suggested another way to estimate the e.d.r. space which can handle such symmetric cases: principal Hessian directions (PHD). However, this method uses the normality of the vector  $X$ . As in the SIR case, we can extend this method, using score functions to use it for any distribution, which we will refer to as SPHD, which we now present.

## 2.2 SPHD: Sliced principal Hessian directions

Before presenting our new moment which will lead to the SPHD method, we consider the non-sliced method, which is based on Assumptions **(A1)** and **(A3)** and score functions (the method based on the Gaussian assumption will be derived later as corollaries). The method of [17], which we refer to as “PHD+” is based on the following lemma (we reproduce the proof for readability):

**Lemma 3** (second-order score moment (PHD+) [17]). *Assume **(A1)** and **(A3)**. Then  $\mathbb{E}(\mathcal{S}_2(x)y)$  has a column space included in the e.d.r. subspace.*

*Proof.* Since  $y = f(x) + \varepsilon$ , and  $\varepsilon$  is independent of  $x$ , we have

$$\begin{aligned} \mathbb{E}(y\mathcal{S}_2(x)) &= \mathbb{E}(f(x))\mathcal{S}_2(x) = \int \frac{\nabla^2 p(x)}{p(x)} p(x) f(x) dx = \\ &= \int \nabla^2 p(x) \cdot f(x) dx = \int p(x) \cdot \nabla^2 f(x) dx = \mathbb{E}[\nabla^2 f(x)], \end{aligned}$$

using integration by parts and the decay of  $p(x)$  and  $\nabla p(x)$  for  $\|x\| \rightarrow \infty$ . This leads to the desired result since  $\nabla^2 f(x) = w \nabla^2 g(w^\top x) w^\top$ . This was proved by Li [20] for normal distributions.  $\square$

**Failure modes.** The method does not work properly if  $\text{rank}(\mathbb{E}(\nabla^2 g(w^\top x))) < k$ . For example, if  $g$  is linear function,  $\mathbb{E}(\nabla^2 g(w^\top x)) \equiv 0$  and the estimated e.d.r. space is degenerated. Moreover, the method fails in symmetric cases, for example, if  $g$  is an odd function with respect to any variable and  $p(x)$  is even function, then  $\text{rank}(\mathbb{E}(\nabla^2 g(w^\top x))) < k$ .

We can now present our second new lemma, the proof of which relies on similar arguments as for PHD [20] but extended to score functions:

**Lemma 4** (SPHD moment). *Assume **(A1)** and **(A3)**. Then,  $\mathbb{E}(\mathcal{S}_2(x)|y)$  has a column space within the e.d.r. subspace almost surely.*

*Proof.* We consider any  $a \in \mathbb{R}^d$  and  $b \in \mathbb{R}^d$  orthogonal to the e.d.r. subspace, and prove, that  $a^\top \mathbb{E}(\mathcal{S}_2(x)|y)b = 0$ . We use the same transform of coordinates as in the proof of Lemma 2:  $\tilde{x} = \tilde{w}^\top x \in \mathbb{R}^d$ . Then  $\nabla^2 p(x) = \tilde{w} \nabla^2 \tilde{p}(\tilde{x}) \tilde{w}^\top$ ,  $\tilde{b} = \tilde{w}^\top b = (0, \dots, 0, \tilde{b}_{k+1}, \dots, \tilde{b}_d)$  and we will prove, that

$\tilde{w} \cdot \mathbb{E}(a^\top \mathcal{S}_2(x)b|w^\top x) = 0$  almost surely, and  $\tilde{w}^\top \tilde{\mathcal{S}}_2(\tilde{x})\tilde{w} = \frac{\tilde{w}^\top \nabla^2 \tilde{p}(\tilde{x})\tilde{w}}{\tilde{p}(\tilde{x})} = \frac{\nabla^2 p(x)}{p(x)} = \mathcal{S}_2(x)$ . It is sufficient to show, that for all  $\tilde{x}_1, \dots, \tilde{x}_k$ :

$$\int_{\mathbb{R}^{d-k}} \tilde{a}^\top \cdot \tilde{\mathcal{S}}_2(\tilde{x}) \cdot b \cdot \tilde{p}(\tilde{x}_1, \dots, \tilde{x}_d) d\tilde{x}_{k+1} \dots d\tilde{x}_d = 0.$$

We have:

$$\begin{aligned} \int_{\mathbb{R}^{d-k}} \tilde{a}^\top \cdot \tilde{\mathcal{S}}_2(\tilde{x}) \cdot b \cdot \tilde{p}(\tilde{x}_1, \dots, \tilde{x}_d) d\tilde{x}_{k+1} \dots d\tilde{x}_d &= \tilde{a}^\top \cdot \left[ \int_{\mathbb{R}^{d-k}} \nabla^2 \tilde{p}(\tilde{x}) \cdot d\tilde{x}_{k+1} \dots d\tilde{x}_d \right] \cdot \tilde{b} \\ &= \sum_{\substack{1 \leq i \leq d \\ k+1 \leq j \leq d}} \tilde{a}_i \tilde{b}_j \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \dots \left[ \int_{-\infty}^{\infty} \frac{\partial^2 \tilde{P}(\tilde{x})}{\partial \tilde{x}_i \partial \tilde{x}_j} \cdot d\tilde{x}_j \right] \cdot \prod_{\substack{k+1 \leq t \leq d \\ t \neq j}} d\tilde{x}_t = 0, \end{aligned}$$

because for any  $j \in \{k+1, \dots, n\}$ :  $\int_{-\infty}^{\infty} \frac{\partial^2 \tilde{P}(\tilde{x})}{\partial \tilde{x}_i \partial \tilde{x}_j} \cdot d\tilde{x}_j = 0$  due to Assumption **(A3)**.  $\square$

In order to combine several values of  $y$ , we will estimate  $\mathcal{V}_2 = \mathbb{E}\left([\mathbb{E}(\mathcal{S}_2(x)|y)]^2\right)$ , which is the expectation with respect to  $y$  of the square of the conditional expectation from Lemma 4, as well as  $\mathcal{V}'_2 = \mathbb{E}\left(y^2 [\mathbb{E}(\mathcal{S}_2(x)|y)]^2\right)$ , and consider the  $k$  largest eigenvectors. From the lemma above, this matrix has a column space included in the e.d.r. subspace, thus, if it has rank  $k$ , we get exact recovery by an eigenvalue decomposition.

**Effect of slicing.** We now study the effect of slicing and show that in the population case, it is superior to the non-sliced version, as it recovers the true e.d.r. subspace in more situations.

**Proposition 2.** *Assume **(A1)** and **(A3)**. The matrix  $w$  may be recovered from the moment in Lemma 3 (up to right linear transform) if and only if  $\mathbb{E}[\nabla^2 g(w^\top x)]$  has full rank. If this condition is satisfied, then SPHD also recovers  $w$  up to scale.*

*Proof.* The first statement is a consequence of the proof of Lemma 3. Moreover, using Lowner-Heinz Theorem about operator convexity [26]:

$$\mathcal{V}'_2 = \mathbb{E}[\mathbb{E}(y\mathcal{S}_2(x)|y)^2] \succcurlyeq [\mathbb{E}[\mathbb{E}(y\mathcal{S}_2(x)|y)]]^2 = [\mathbb{E}(y\mathcal{S}_2(x))]^2,$$

showing that the new moment is dominating the PHD moment, thus implying that

$$\text{rank}[\mathcal{V}'_2] \geq \text{rank}[\mathbb{E}(y\mathcal{S}_2(x))].$$

Therefore, if  $\text{rank}[\mathbb{E}(y\mathcal{S}_2(x))] = k$ , then  $\text{rank}[\mathcal{V}'_2] = k$  (note that there is not such a proof for  $\mathcal{V}_2$ ).  $\square$

**Elliptically symmetric distributions.** When  $x$  is a standard Gaussian random variable, then  $\mathcal{S}_2(x) = -I + xx^\top$ , and thus  $\mathbb{E}\left([\mathbb{E}(\mathcal{S}_2(x)|y)]^2\right) = \mathbb{E}\left([I - \text{Cov}(x|y)]^2\right)$ , and we recover the sliced average variance estimation (SAVE) method by Cook and Weisberg [8]. However, our method applies to all distributions (with known score functions).

### 2.3 Relationship between first and second order methods

All considered methods have their own failure modes. The simplest one: ADE works only in single-index model and has quite a simple working condition :  $\mathbb{E}[g'(w^\top x)] \neq 0$ . Sliced improvement (e.g., SADE) of this algorithm has a better performance, however it still suffers from symmetric cases, when the inverse regression curve is partly degenerated. PHD+ can not work properly in linear models and symmetric cases. SPHD is stronger than PHD+ and potentially has the widest application area among four described methods. See summary in Table 1.

| method | main equation  | score  | sliced | single-index   | multi-index   |
|--------|--|--------|--------|--|---|
| ADE    | $\mathbb{E}(\mathcal{S}_1(x)y)$  | first  | no     | $\mathbb{E}[g'(w^\top x)] \neq 0$  | does not work   |
| SADE   | $\mathbb{E}_y \left[ \mathbb{E}(\mathcal{S}_1(x) y)^{\otimes 2} \right]$ | first  | yes    | $\mathbb{E}_y \left[ \ \mathbb{E}(\mathcal{S}_1(x) y)\ ^2 \right] > 0$         | $\text{rank } \mathbb{E}_y \left[ \mathbb{E}(\mathcal{S}_1(x) y)^{\otimes 2} \right] = k$ |
| PHD+   | $\mathbb{E}(\mathcal{S}_2(x)y)$  | second | no     | $\mathbb{E}[g''(w^\top x)] \neq 0$   | $\text{rank } \mathbb{E}[\nabla^2 g(x)] = k$  |
| SPHD   | $\mathbb{E}_y \left[ \mathbb{E}((\mathcal{S}_2(x) y)^2) \right]$         | second | yes    | $\mathbb{E}_y \left[ \text{tr} \mathbb{E}((\mathcal{S}_2(x) y)^2) \right] > 0$ | $\text{rank } \mathbb{E}_y \left[ \mathbb{E}((\mathcal{S}_2(x) y)^2) \right] = k$         |

Table 1: Information about different methods using scores.

## 3 Estimation from finite sample

In this section, we consider finite sample estimators for the moments we have defined in Section 2. Since our extensions are combinations of existing techniques (using score functions and slicing) our finite-sample estimators naturally rely on existing work [16, 29].

In this section, we assume that the score function is known. We consider learning the score function in Section 4.

### 3.1 Estimator and algorithm for SADE

Our goal is to provide an estimator for  $\mathcal{V}_1 = \mathbb{E} \left[ \mathbb{E}(\mathcal{S}_1(x)|y) \mathbb{E}(\mathcal{S}_1(x)|y)^\top \right] = \text{Cov} \left[ \mathbb{E}(\mathcal{S}_1(x)|y) \right]$  given a finite sample  $(x_i, y_i)$ ,  $i = 1, \dots, n$ . A similar estimator for  $\mathcal{V}'_1$  could be derived.

We consider slicing the real numbers in  $H$  different *slices*,  $I_1, \dots, I_H$ , which are contiguous intervals that form a partition of  $\mathbb{R}$  (or of the range of all  $y_i$ ,  $i = 1, \dots, n$ ). We then compute an estimator of the conditional expectation  $(\mathcal{S}_1)_h = \mathbb{E}(\mathcal{S}_1(x)|y \in I_h)$  with empirical averages: denoting  $\hat{p}_h$  the empirical proportion of  $y_i$ ,  $i = 1, \dots, n$ , that fall in the slice  $I_h$  (which is assumed to be strictly positive), we estimate  $(\mathcal{S}_1)_h = \mathbb{E}(\mathcal{S}_1(x)|y \in I_h)$  by

$$(\hat{\mathcal{S}}_1)_h = \frac{1}{n\hat{p}_h} \sum_{i=1}^n \mathbf{1}_{y_i \in I_h} \mathcal{S}_1(x_i).$$

We then estimate  $\mathcal{V}_1 = \mathbb{E} \left[ \mathbb{E}(\mathcal{S}_1(x)|y) \mathbb{E}(\mathcal{S}_1(x)|y)^\top \right]$  through:

$$\hat{\mathcal{V}}_1 = \sum_{h=1}^H \hat{p}_h (\hat{\mathcal{S}}_1)_h (\hat{\mathcal{S}}_1)_h^\top.$$

We show in Section 3.3 that  $\hat{\mathcal{V}}_1$  is a consistent estimator of  $\mathcal{V}_1$  for the particular choice of slices based on the cumulative distribution function (see below).

The final SADE algorithm is thus the following:

- Divide the range of  $y_1, \dots, y_n$  into  $H$  slices  $I_1, \dots, I_H$ . Let  $\hat{p}_h > 0$  be the proportion of  $y_i$ ,  $i = 1, \dots, n$ , that fall in slice  $I_h$ .
- For each slice  $I_h$ , compute the sample mean  $(\hat{\mathcal{S}}_1)_h$  of  $\mathcal{S}_1(x)$ :  $(\hat{\mathcal{S}}_1)_h = \frac{1}{n\hat{p}_h} \sum_{i=1}^n \mathbf{1}_{y_i \in I_h} \mathcal{S}_1(x_i)$ .
- Compute the weighted covariance matrix  $\hat{\mathcal{V}}_1 = \sum_{h=1}^H \hat{p}_h (\hat{\mathcal{S}}_1)_h (\hat{\mathcal{S}}_1)_h^\top$ .
- Find the  $k$  largest eigenvalues and let  $\hat{w}_1, \dots, \hat{w}_k$  be eigenvectors in  $\mathbb{R}^d$  corresponding to these eigenvalues.

**Choice of slices.** There are different ways to choose slices  $I_1, \dots, I_H$ :

- all slices have the same length, that is we choose the maximum and the minimum of  $y_1, \dots, y_n$ , and divide the range of  $y$  into  $H$  equal slices (for simplicity, we assume that  $n$  is a multiple of  $H$ ),
- we can also use the distribution of  $y$  to ensure a balanced distribution of observations in each slice, and choose  $I_h = (\hat{F}_y^{-1}((h-1)/H), \hat{F}_y^{-1}(h/H)]$ , where  $\hat{F}_y(t) = \frac{1}{n} \sum_{i=1}^n \mathbf{1}_{y_i \leq t}$  is the empirical distribution function of  $y$ . If  $n$  is a multiple  $H$ , there are exactly  $c = n/H$  observations per slice.

Later on in our experiments, we use the second way, where every slice has  $c = n/H$  points, and our consistency result applies to this situation as well.

**Computational complexity.** The first step of the algorithm requires  $O(n)$  elementary operations, the second  $O(nd)$  operations, the third  $O(Hd^2)$  and the fourth  $O(kd^2)$  operations. The overall dependence on dimension  $d$  is quadratic.

### 3.2 Estimator and algorithm for SPHD

We follow the same approach as for the SADE algorithm above, leading to the following algorithm, which estimates  $\mathcal{V}_2 = \mathbb{E}\left(\left[\mathbb{E}(\mathcal{S}_2(x)|y)\right]^2\right)$  and computes its principal eigenvectors. Note, that  $\mathbb{E}[\mathbb{E}(\mathcal{S}_2(x)|y \in I_h)] = \mathbb{E}[\mathcal{S}_2(x)] = 0$ .

- Divide the range of  $y_1, \dots, y_n$  into  $H$  slices  $I_1, \dots, I_H$ . Let  $\hat{p}_h > 0$  be the proportion of  $y_i$ ,  $i = 1, \dots, n$ , that fall in slice  $I_h$ .
- For each slice, compute the sample mean  $(\hat{\mathcal{S}}_2)_h$  of  $\mathcal{S}_2(x)$ :  $(\hat{\mathcal{S}}_2)_h = \frac{1}{n\hat{p}_h} \sum_{i=1}^n \mathbf{1}_{y_i \in I_h} \mathcal{S}_2(x_i)$ .
- Compute the weighted covariance matrix  $\hat{\mathcal{V}}_2 = \sum_{h=1}^H \hat{p}_h (\hat{\mathcal{S}}_2)_h^2$ , find the  $k$  largest eigenvalues and let  $\hat{w}_1, \dots, \hat{w}_k$  be eigenvectors corresponding to these eigenvalues.

The matrix  $\hat{\mathcal{V}}_2$  is then an estimator of  $\mathbb{E}\left(\left[\mathbb{E}(\mathcal{S}_2(x)|y)\right]^2\right)$ .

**Computational complexity.** The first step of the algorithm requires  $O(n)$  elementary operations, the second  $O(nd^2)$  operations, the third  $O(Hd^3)$  and the fourth  $O(kd^2)$  operations. The overall dependence on dimension  $d$  is cubic, hence the method is slower than SADE.

### 3.3 Consistency for the SADE estimator and algorithm

In this section, we prove the consistency of the SADE moment estimator and the resulting algorithm, when the score function is known. Following Hsing and Carroll [16] and Xhu and Ng [29], we can get  $\sqrt{n}$ -consistency for the SADE algorithm with very broad assumptions regarding the problem.

In this section, we focus on the simplest set of assumptions to pave the way to the analysis for the nuclear norm in future work. The key novelty compared to [16, 29] is a precise *non-asymptotic* analysis with precise constants.

We make the following assumptions:

- (L1) The function  $m : \mathbb{R} \rightarrow \mathbb{R}^d$  such that  $\mathbb{E}(\ell(x)|y) = m(y)$  is  $L$ -Lipschitz-continuous.
- (L2) The random variable  $y \in \mathbb{R}$  is sub-Gaussian, i.e, such that  $\mathbb{E}e^{t(y-Ey)} \leq e^{\tau_y^2 t^2/2}$ , for some  $\tau_y > 0$ .
- (L3) The random variables  $\eta_j = \ell_j(x) - m_j(y) \in \mathbb{R}$  are sub-Gaussian, i.e, such that  $\mathbb{E}e^{t\eta_j} \leq e^{\tau_\eta^2 t^2/2}$  for each component  $j \in \{1, \dots, d\}$ , for some  $\tau_\eta > 0$ .

Now we formulate and proof the main theorem, where  $\|\cdot\|_*$  is the nuclear norm, defined as  $\|A\|_* = \text{tr}(\sqrt{A^T A})$ :

**Theorem 1.** *Under assumptions (L1), (L2), (L3) we get the following bound on  $\|\hat{\mathcal{V}}_1 - \mathcal{V}_1\|_*$ : for any  $\delta < \frac{1}{n}$ , with probability not less than  $1 - \delta$ :*

$$\|\hat{\mathcal{V}}_1 - \mathcal{V}_1\|_* \leq \frac{195d\tau_\eta^2}{\sqrt{n}} \sqrt{\log \frac{12d^2}{\delta}} + \frac{8L^2\tau_y^2 + 16\tau_\eta\tau_yL\sqrt{d} + 157\tau_\eta^2d}{n} \log^2 \frac{16d^2n}{\delta}.$$

The proof of the theorem can be found in Appendix A.2. The leading term is proportional to  $\frac{d\tau_\eta^2}{\sqrt{n}}$ , with a tail which is sub-Gaussian. We thus get a  $\sqrt{n}$ -consistent estimator or  $\mathcal{V}_1$ .

## 4 Learning score functions

All previous methods can work only if we know the score function of first or second order. In practice, we do not have such information, and we have to learn score functions from sample data. In this section, we only consider the first-order score function  $\ell(x) = \mathcal{S}_1(x) = -\nabla \log p(x)$ .

We first present the score matching approach of [1], and then apply it to our problem.

### 4.1 Score matching to estimate score from data

Given the true score function  $\ell(x) = \mathcal{S}_1(x) = -\nabla \log p(x)$  and some i.i.d. data generated from  $p(x)$ , score matching aims at estimating the parameter of a model for the score function  $\hat{\ell}(x)$ , by minimizing a empirical quantity aiming to estimate

$$\mathcal{R}_{\text{score}}(\hat{\ell}) = \frac{1}{2} \int_{\mathbb{R}^d} p(x) \|\ell(x) - \hat{\ell}(x)\|^2 dx.$$

As is, the quantity above leads to consistent estimation (i.e., pushing  $\hat{\ell}$  close to  $\ell$ ), but seems to need the knowledge of the true score  $\ell(x)$ . A key insight from [1] is to use integration by parts to

get (assuming the integrals exist):

$$\begin{aligned}\mathcal{R}_{\text{score}}(\hat{\ell}) &= \frac{1}{2} \int_{\mathbb{R}^d} p(x) [\|\ell(x)\|^2 + \|\hat{\ell}(x)\|^2 + 2\hat{\ell}(x)^\top \nabla \log p(x)] dx \\ &= \frac{1}{2} \int_{\mathbb{R}^d} p(x) \|\ell(x)\|^2 dx + \frac{1}{2} \int_{\mathbb{R}^d} p(x) \|\hat{\ell}(x)\|^2 dx + \int_{\mathbb{R}^d} \hat{\ell}(x)^\top \nabla p(x) dx \\ &= \frac{1}{2} \int_{\mathbb{R}^d} p(x) \|\ell(x)\|^2 dx + \frac{1}{2} \int_{\mathbb{R}^d} p(x) \|\hat{\ell}(x)\|^2 dx - \int_{\mathbb{R}^d} (\nabla \cdot \hat{\ell})(x) p(x) dx,\end{aligned}$$

by integration by parts, where  $(\nabla \cdot \hat{\ell})(x) = \sum_{i=1}^d \frac{\partial \hat{\ell}_i}{\partial x_i}(x)$  is the divergence of  $\hat{\ell}$  at  $x$  [2].

The first part of the last right hand side does not depend on  $\hat{\ell}$  while the two other parts are expectations under  $p(x)$  of quantities that only depend on  $\hat{\ell}$ . Thus it can be well approximated, up to a constant, by:

$$\hat{\mathcal{R}}_{\text{score}}(\hat{\ell}) = \frac{1}{2n} \sum_{i=1}^n \|\hat{\ell}(x_i)\|^2 - \frac{1}{n} \sum_{i=1}^n (\nabla \cdot \hat{\ell})(x_i).$$

**Parametric assumption.** If we assume that the score is linear combination of finitely many basis functions, we will get a consistent estimator of these parameters. That is, we make the following assumption:

- (A4) The score function  $\ell(x)$  is a linear combination of known basis functions  $\psi^j(x)$ ,  $j = 1, \dots, m$ , where  $\psi^j : \mathbb{R}^d \rightarrow \mathbb{R}^d$ , that is  $\ell(x) = \sum_{j=1}^m \psi^j(x) \theta_j^*$ , for some  $\theta^* \in \mathbb{R}^m$ . We assume that score function and its derivatives are squared-integrable with respect to  $p(x)$ .

In this paper, we consider for simplicity a parametric assumption for the score. In order to go towards non-parametric estimation, we would need to let the number  $m$  of basis functions to grow with  $n$  (exponentially with no added assumptions), and this is an interesting avenue for future work. In simulations in Section 5, we consider a simple set of basis function which are localized functions around observations; these can approximate reasonably well in practice most densities and led to good estimation of the e.d.r. subspace.

We introduce the notation

$$\Psi(x) = \begin{pmatrix} \psi_1^1(x) & \cdots & \psi_d^1(x) \\ \vdots & \ddots & \vdots \\ \psi_1^m(x) & \cdots & \psi_d^m(x) \end{pmatrix} \in \mathbb{R}^{m \times d},$$

so that the score function  $\hat{\ell}$  we wish to estimate has the form

$$\hat{\ell}(x) = \Psi(x)^\top \theta \in \mathbb{R}^d.$$

We also introduce the notation  $(\nabla \cdot \Psi)(x) = \begin{pmatrix} (\nabla \cdot \Psi^1)(x) \\ \vdots \\ (\nabla \cdot \Psi^m)(x) \end{pmatrix} \in \mathbb{R}^m$ , so that  $(\nabla \cdot \hat{\ell})(x) = \theta^\top (\nabla \cdot \Psi)(x)$ .

The empirical score function may then be written as:

$$\hat{\mathcal{R}}_{\text{score}}(\theta) = \frac{1}{2} \theta^\top \left( \frac{1}{n} \sum_{i=1}^n \Psi(x_i) \Psi(x_i)^\top \right) \theta - \theta^\top \left( \frac{1}{n} \sum_{i=1}^n (\nabla \cdot \Psi)(x_i) \right), \quad (4.1)$$

which is a quadratic function of  $\theta$  and can thus be minimized by solving a linear system in running time  $O(m^3 + m^2 dn)$  (to form the matrix and to solve the system).

Given standard results regarding the convergence of  $\frac{1}{n} \sum_{i=1}^n \Psi(x_i) \Psi(x_i)^\top \in \mathbb{R}^{m \times m}$  to its expectation and of  $\frac{1}{n} \sum_{i=1}^n (\nabla \cdot \hat{\ell})(x_i) \in \mathbb{R}^m$  to its expectation, we get a  $\sqrt{n}$ -consistent estimation of  $\theta^*$  under simple assumptions (see Theorem 2).

## 4.2 Score matching for sliced inverse regression: two-step approach

We can now combine our linear parametrization of the score with the SIR approach outlined in Section 3. The true conditional expectation is

$$\mathbb{E}(\ell(x)|y) = \sum_{j=1}^m \mathbb{E}(\psi^j(x)|y)\theta_j^*,$$

and belongs to the e.d.r. subspace. We consider  $H$  different slices  $I_1, \dots, I_H$ , and the following estimator, which simply replaces the true score by the estimated score (i.e.,  $\theta^*$  by  $\theta$ ), and highlights the dependence in  $\theta$ .

We introduce the notation

$$\hat{\Psi}_h = \frac{1}{|I_h|} \sum_{i=1}^n \mathbf{1}_{y_i \in I_h} \Psi(x_i) \in \mathbb{R}^{m \times d},$$

so that  $\hat{\ell}_h = \hat{\Psi}_h^\top \theta \in \mathbb{R}^d$ . Thus, we have the estimator

$$\hat{\mathcal{V}}_1(\theta) = \sum_{h=1}^H \hat{p}_h \hat{\Psi}_h^\top \theta \theta^\top \hat{\Psi}_h \in \mathbb{R}^{d \times d}. \quad (4.2)$$

In the two-step approach, we first solve the score matching optimisation problem to obtain an estimate for the optimal parameters  $\theta^*$  and then use them to get the  $k$  largest eigenvectors of covariance matrix  $\hat{\mathcal{V}}_1$ . This approach works well in low dimensions when the score function can be well approximated; otherwise, we may suffer from the curse of dimensionality: if we want a good approximation of the score function, we would need an exponential number of basis functions. In Section 4.3, we consider a direct approach aiming at circumventing this problem.

**Consistency.** Let also provide the result of consistency in the case of unknown score function under Assumption (A4) for the two-step algorithm. We will make the additional assumptions:

- (M1) The random variables  $\Psi_i^j(x) \in \mathbb{R}$  are sub-Gaussian, i.e, such that  $\mathbb{E}e^{t(\Psi_i^j(x) - E\Psi_i^j(x))} \leq e^{\tau_\Psi^2 t^2/2}$ , for some  $\tau_\Psi > 0$ .
- (M2) The random variables  $(\nabla \cdot \Psi^i)(x)$  are sub-Gaussian, i.e, such that  $\mathbb{E}e^{t((\nabla \cdot \Psi^i)(x) - E(\nabla \cdot \Psi^i)(x))} \leq e^{\tau_{\nabla \Psi}^2 t^2/2}$ , for some  $\tau_{\nabla \Psi} > 0$ .
- (M3) The matrix  $\mathbb{E}[\Psi(x)\Psi(x)^\top]$  is not degenerated and we let  $\lambda_0$  denote its minimal eigenvalue.

**Theorem 2.** *Let  $\hat{\theta}$  be the estimated  $\theta$ , obtained on the first step of algorithm. Under Assumptions (A1), (A2), (A4), (L1), (L2), (L3) and (M1), (M2), (M3), for  $\delta \leq 1/n$  and  $n$  large enough, that is,  $n > c_1 + c_2 \log \frac{1}{\delta}$  for some positive constants  $c_1$  and  $c_2$  not depending on  $n$  and  $\delta$ :*

$$\begin{aligned} \|\mathcal{V}_1(\theta^*) - \hat{\mathcal{V}}_1(\hat{\theta})\|_* &\leq \frac{1}{\sqrt{n}} \sqrt{2 \log \frac{12m^2 d}{\delta}} \\ &\times \left[ 195d\tau_\eta^2 + \frac{9m}{2} \mathbb{E}\|\Psi(x)\|_2^2 \cdot \|\theta^*\| \left( \frac{2\tau_{\nabla \Psi} \sqrt{m}}{\lambda_0} + \frac{4\|b\| \tau_\Psi^2 \sqrt{m^3 d}}{\lambda_0^2} \right) \right] + O\left(\frac{1}{n}\right). \end{aligned}$$

Now, let us formulate and proof non-asymptotic result about the real and the estimated e.d.r. spaces. We need to define a notion of distance between subspaces spanned by two sets of vectors. We use the square trace error  $R^2(w, \hat{w})$  [14]:

$$R^2(w, \hat{w}) = 1 - \frac{1}{k} \text{tr}[w \cdot \hat{w}],$$

where  $w \in \mathbb{R}^{k \times d}$  and  $\hat{w} \in \mathbb{R}^{k \times d}$  both have orthonormal columns. It is always between zero and one, and equal to zero if and only if  $w = \hat{w}$ . This distance is close related to *principal angles* notion:

$$\sin \Theta(\hat{w}^\top w) = \text{diag}(\sin(\cos^{-1} \sigma_1), \dots, \sin(\cos^{-1} \sigma_d)),$$

where  $\sigma_1, \dots, \sigma_d$  are the singular values of  $\hat{w}^\top w$ . Actually,  $\mathbb{R}(w, \hat{w}) \cdot \sqrt{k} = \|\sin \Theta(\hat{w}^\top w)\|_F$

Now, we can formulate Davis-Kahan “sin  $\theta$  theorem” [24, Theorem V.3.6]:

**Theorem 3.** *Let  $\Sigma$  and  $\hat{\Sigma} \in \mathbb{R}^{d \times d}$  be symmetric, with eigenvalues  $\lambda_1 \geq \dots \geq \lambda_d$  and  $\hat{\lambda}_1, \dots, \hat{\lambda}_d$  respectively. Fix  $1 \leq r \leq s \leq d$ , let  $k = s - r + 1$ , and let  $U = (u_r, u_{r+1}, \dots, u_s) \in \mathbb{R}^{d \times k}$  and  $\hat{U} = (\hat{u}_r, \hat{u}_{r+1}, \dots, \hat{u}_s) \in \mathbb{R}^{d \times k}$  have orthonormal columns satisfying  $\Sigma u_j = \lambda_j u_j$  and  $\hat{\Sigma} \hat{u}_j = \hat{\lambda}_j \hat{u}_j$  for  $j = r, \dots, s$ . Let  $\delta = \inf\{|\hat{\lambda} - \lambda| : \lambda \in [\lambda_s, \lambda_r], \hat{\lambda} \in (-\infty, \hat{\lambda}_{s+1}] \cup [\hat{\lambda}_{r-1}, +\infty)\}$ , where  $\hat{\lambda}_0 = +\infty$  and  $\hat{\lambda}_{p+1} = -\infty$ . Assume, that  $\delta > 0$ , then:*

$$R(U, \hat{U}) \leq \frac{\|\hat{\Sigma} - \Sigma\|_F}{\delta \sqrt{k}}. \quad (4.3)$$

As a corollary of Theorem 3 we can derive, that  $R(w, \hat{w}) \leq \frac{\|\mathcal{V}_1(\theta^*) - \hat{\mathcal{V}}_1(\hat{\theta})\|_F}{|\lambda_k - \hat{\lambda}_{k+1}|}$ , where  $w$  and  $\hat{w}$  are the real and the estimated e.d.r. spaces respectively. Using Weyl’s inequality [24] : if  $\|\mathcal{V}_1(\theta^*) - \hat{\mathcal{V}}_1(\hat{\theta})\|_2 < \varepsilon \Rightarrow |\hat{\lambda}_i - \lambda_i| < \varepsilon$  for all  $i = 1, \dots, d$  and taking  $\varepsilon = (\lambda_k - \lambda_{k+1})/2 = \lambda_k/2$  we get:

$$R(w, \hat{w}) \leq \frac{2\|\mathcal{V}_1(\theta^*) - \hat{\mathcal{V}}_1(\hat{\theta})\|_*}{\lambda_k}, \text{ if } \|\mathcal{V}_1(\theta^*) - \hat{\mathcal{V}}_1(\hat{\theta})\|_F < \lambda_k/2,$$

because  $\|\cdot\|_F \leq \|\cdot\|_*$ . We can now formulate our main theorem for the analysis of the SADE algorithm:

**Theorem 4.** *Under assumptions (A1), (A2), (A4), (L1), (L2), (L3), (M1), (M2), (M3) and (K1) The matrix  $\mathcal{V}_1$  has a rank  $k$ :  $\lambda_k > 0$ .*

*For  $\delta \leq 1/n$  and  $n$  large enough:  $n > c_1 + c_2 \log \frac{1}{\delta}$  for some positive constants  $c_1$  and  $c_2$  not depending on  $n$  and  $\delta$ :*

$$R(\hat{w}, w) \leq \frac{2}{\sqrt{n} \lambda_k} \sqrt{2 \log \frac{12m^2 d}{\delta}} \\ \times \left[ 195d\tau_\eta^2 + \frac{9m}{2} \mathbb{E} \|\Psi(x)\|_2^2 \cdot \|\theta^*\| \left( \frac{2\tau_{\nabla \Psi} \sqrt{m}}{\lambda_0} + \frac{4\|b\| \tau_{\Psi}^2 \sqrt{m^3 d}}{\lambda_0^2} \right) \right] + O\left(\frac{1}{n}\right).$$

We thus obtain a convergence rate in  $1/\sqrt{n}$ , with an explicit dependence on all constants of the problem.

### 4.3 Score matching for SIR: direct approach

We can also try to combine these two steps to avoid the “curse of dimensionality”. Our estimation of the score, i.e., of the parameter  $\theta$  is done only to be used within the SIR approach where we expect the matrix  $\hat{\mathcal{V}}_1$  to have rank  $k$ . Thus when estimating  $\theta$  by minimizing  $\hat{\mathcal{R}}_{\text{score}}(\theta)$ , we may add a regularization that penalizes large ranks for  $\hat{\mathcal{V}}_1(\theta) = \sum_{h=1}^H \hat{p}_h \hat{\Psi}_h^\top \theta \theta^\top \hat{\Psi}_h$ , where we highlight the dependence on  $\theta \in \mathbb{R}^m$ . By enforcing the low-rank constraint, our aim is to circumvent a potential poor estimation of the score function, which could be enough for the task of estimating the e.d.r. space (we see a better behavior in our simulations in Section 5).

We may thus also consider the  $H$  vectors  $\hat{\Psi}_h^\top \theta \in \mathbb{R}^d$ ,  $h \in \{1, \dots, H\}$  and put them in a matrix  $\mathcal{A}(\theta) = (\sqrt{\hat{p}_1} \hat{\Psi}_1^\top \theta, \dots, \sqrt{\hat{p}_H} \hat{\Psi}_H^\top \theta) \in \mathbb{R}^{d \times H}$ .

Consider also matrix  $\mathcal{A}(\theta)^\top$ . Its  $k$ -th column can be expressed as  $[\sqrt{\hat{p}_1} \cdot \hat{\Psi}_{1,k}^\top \cdot \theta, \dots, \sqrt{\hat{p}_H} \cdot \hat{\Psi}_{H,k}^\top \cdot \theta]^\top \in \mathbb{R}^H$ , where  $\hat{\Psi}_{j,k}^\top \in \mathbb{R}^d$  is the  $k$ -th row of  $\hat{\Psi}_j^\top$ . Combining rows  $\hat{\Psi}_{j,k}^\top$  into the matrix  $\check{\Psi}_k^\top \in \mathbb{R}^{H \times m}$ , we obtain:  $\mathcal{A}(\theta)^\top = D_p \cdot (\check{\Psi}_1^\top \theta, \dots, \check{\Psi}_d^\top \theta)$ , where  $D_p = \text{diag}(\sqrt{\hat{p}_1}, \dots, \sqrt{\hat{p}_H})$ .

We may then penalize the nuclear norm of  $\mathcal{A}(\theta)$ , or potentially consider norms that take into account that we look for a rank  $k$  (e.g., the  $k$ -support norm on the spectrum of  $\mathcal{A}(\theta)$  [22]). We have,

$$\|\mathcal{A}(\theta)\|_* = \text{tr}(\mathcal{A}(\theta)\mathcal{A}(\theta)^\top)^{1/2} = \text{tr}[\hat{\mathcal{V}}_1(\theta)^{1/2}],$$

or

$$\|\mathcal{A}(\theta)\|_* = \text{tr}(\mathcal{A}(\theta)^\top \mathcal{A}(\theta)^\top)^{1/2} = \text{tr}[U(\theta)^{1/2}],$$

where  $U(\theta) = D_p \cdot \left[ \sum_{j=1}^d \check{\Psi}_j^\top \theta \theta^\top \check{\Psi}_j \right] \cdot D_p \in \mathbb{R}^{H \times H}$ .

Combining two penalties, we have a convex optimization task:

$$\hat{\mathcal{R}}(\theta) = \hat{\mathcal{R}}_{\text{score}}(\theta) + \lambda \text{tr}[\hat{\mathcal{V}}_1(\theta)^{1/2}]. \quad (4.4)$$

**Efficient algorithm.** Following [3], we consider reweighted least-squares algorithms. The trace norm admits the variational form (see [4]):

$$\|W\|_* = \frac{1}{2} \inf_{D > 0} \text{tr}(W^\top D^{-1} W + D).$$

The optimization problem (4.4) can be reformulated in the following way:

$$\begin{aligned} \theta \leftarrow \underset{\theta}{\text{argmin}} \quad & \hat{\mathcal{R}}_{\text{score}}(\theta) + \frac{\lambda}{2} \text{tr}(\mathcal{A}(\theta)^\top D^{-1} \mathcal{A}(\theta)) \quad \text{and} \\ D \leftarrow & (\mathcal{A}(\theta)\mathcal{A}(\theta)^\top + \varepsilon I_d)^{1/2}. \end{aligned}$$

Note that the objective function is a quadratic function of  $\theta$ . Decompose matrix  $\mathcal{A}$  in the form:

$$\mathcal{A}(\theta) = \sum_{k=1}^m \theta_k \mathcal{A}_k, \quad \text{where } \mathcal{A}_k \in \mathbb{R}^{d \times H}.$$

Rearrange regularizer term:

$$\text{tr}(\mathcal{A}(\theta)^\top D^{-1} \mathcal{A}(\theta)) = \sum_{k=1}^m \sum_{l=1}^m \text{tr}[\theta_k \mathcal{A}_k^\top D^{-1} \mathcal{A}_l \theta_l] = \theta^\top \mathcal{Y} \theta,$$

where

$$\mathcal{Y}_{k,l} = \text{tr}[\mathcal{A}_k^\top D^{-1} \mathcal{A}_l].$$

Introduce notation:

$$\begin{aligned} \tilde{\mathcal{A}} &= \left( \text{vect}(\mathcal{A}_1), \dots, \text{vect}(\mathcal{A}_m) \right) \in \mathbb{R}^{dh \times m} \\ \tilde{\mathcal{B}} &= \left( \text{vect}(D^{-1} \mathcal{A}_1), \dots, \text{vect}(D^{-1} \mathcal{A}_m) \right) \in \mathbb{R}^{dh \times m}, \end{aligned}$$

then

$$\mathcal{Y} = \tilde{\mathcal{A}}^\top \tilde{\mathcal{B}}.$$

We can now estimate the complexity of this algorithm. Firstly we need to evaluate quadratic form in  $\hat{\mathcal{R}}_{\text{score}}(\theta)$ : it is a summation of  $n$  multiplications of  $m \times d$  and  $d \times m$  matrices. Complexity of this step is  $O(nm^2d)$ . Secondly, we need to evaluate matrix matrices  $D^{-1}$ ,  $\tilde{\mathcal{A}}$  and  $\tilde{\mathcal{B}}$  using  $O(d^3)$ ,  $O(dHm)$  and  $O(m \times d^2H)$  operations respectively. Next, we need to evaluate matrix  $\mathcal{Y}$ , using  $O(dHm^2)$  operations. Finally, evaluating  $\mathcal{A}(\theta)$  requires  $O(dHm)$  operations,  $\mathcal{A}(\theta)\mathcal{A}(\theta)^\top$  requires  $O(d^2H)$  operations and evaluation of  $D$  requires  $O(d^3)$  operations. Combining complexities, we get  $O(dHm^2 + md^2H + d^3 + nm^2d)$  operations.

## 5 Experiments

In this section we provide numerical experiments for SADE, PHD+ and SPHD on different functions  $f$ . We denote the true and estimated e.d.r. subspaces as  $\mathcal{E}$  and  $\hat{\mathcal{E}}$  respectively, defined from  $w$  and  $\hat{w}$ .

### 5.1 Known score functions

Consider a Gaussian mixture model with 2 components in  $\mathbb{R}^d$ :

$$p(x) = \sum_{i=1}^2 \theta_i \cdot \frac{1}{(2\pi)^{d/2} \cdot |\Sigma_i|^{1/2}} \cdot \exp \left\{ -\frac{1}{2} (X - \mu_i)^\top \Sigma_i^{-1} (X - \mu_i) \right\}, \quad (5.1)$$

where  $\theta = (6/10, 4/10)$ ,  $\mu_1 = (\underbrace{-1, \dots, -1}_d)$ ,  $\mu_2 = (\underbrace{1, \dots, 1}_d)$ ,  $\Sigma_1 = I_d$ ,  $\Sigma_2 = 2 \cdot I_d$ . Contour lines of this distribution, when  $d = 2$  are shown in Figure 1.

The error  $\varepsilon$  has a standard normal distribution. To estimate the effectiveness of an estimated e.d.r. subspace, we use the square trace error  $R^2(w, \hat{w})$  [14]:

$$R^2(w, \hat{w}) = 1 - \frac{1}{k} \text{tr}[P \cdot \hat{P}],$$

where  $w$  and  $\hat{w}$  are the real and the estimated e.d.r. vectors respectively.

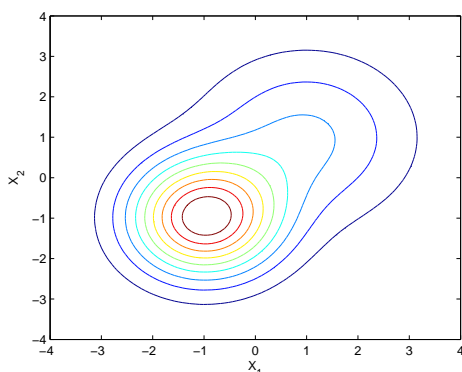

Figure 1: Contour lines of Gaussian mixture pdf in 2D case.

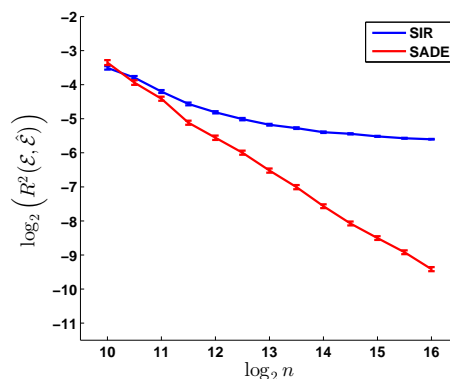

Figure 2: Mean and standard deviation of  $R^2(\mathcal{E}, \hat{\mathcal{E}})$  divided by 10 for the rational function (5.2).

To show the dominance of SADE over SIR (which should only work for elliptically symmetric distributions), we consider the rational multi-index model of the form

$$d = 10; \quad y = \frac{x_1}{1/2 + (x_2 + 2)^2} + \sigma \cdot \varepsilon. \quad (5.2)$$

Here the real e.d.r. space is generated by 2 specific vectors:  $(1, 0, 0, \dots, 0)$  and  $(0, 1, 0, \dots, 0)$ . The number of slices is  $H = 10$ , and we consider numbers of observations  $n$  from  $2^{10}$  to  $2^{16}$  equally spaced in logarithmic scale, and we conduct 100 replicates to obtain means and standard deviations of the logarithms of square trace errors divided by  $\sqrt{100} = 10$  (to assess significance of differences) as shown in Figure 2. Even in this simple model, the ordinary SIR algorithm does not work properly, because the distribution of the inputs  $x$  has no elliptical symmetry. When  $n \rightarrow \infty$ , the squared trace error tends to some nonzero constant depending on the properties of the density function, whereas SADE shows good performance with slope  $-1$  (corresponding to a  $\sqrt{n}$ -consistent estimator).

Now, we compare the ADE, SADE, PHD+ and SPHD methods. It is worth noting two properties which we have already discussed concerning these methods:

1. Sliced methods have a wider application area than unsliced ones: SADE is stronger than ADE and SPHD is stronger than PHD+.
2. SADE can not recover the entire e.d.r. space in several cases, for example, a classification task or symmetric cases. For those cases, we should use second-order methods (i.e., methods based on  $\mathcal{S}_2$ ).

We conduct 3 experiments:

- Rational model (5.2) with  $\sigma = 1/4$ . Results are shown of Figure 3 and we can see, that SPHD works better, than PHD+, that is slicing make the method more robust.
- Classification problem of the form

$$y = 1_{x_1^2 + 2x_2^2 > 4} + \varepsilon/4, \quad \varepsilon \in \mathcal{N}(0, 1). \quad (5.3)$$

We can see, that the error of SADE is close to 0.5 (Figure 4). This means that the method finds only one direction in the e.d.r. space. Moreover, SPHD gave better results than PHD+.

- Linear single-index model in form

$$d = 5; \quad y = x_1 + x_2 + x_3 + x_4 + 0 \cdot x_5 + \varepsilon. \quad (5.4)$$

Both SADE and SPHD show a good performance (Figure 5), while PHD+ can not recover the desired projection due to linearity of the function  $g$ .

## 5.2 Unknown score functions

Now, we conduct numerical experiments for SADE with unknown score functions. We consider a “toy” experiment and first examine results of the 2-step algorithm. We consider again a Gaussian mixture model (5.1) with 2 components in  $\mathbb{R}^2$ , where  $\theta = (0.6, 0.4)$ ,  $\mu_1 = (-0.5, 0.5)$ ,  $\mu_2 = (0.5, 0.5)$ ,  $\Sigma_1 = 0.3 \cdot I_2$ ,  $\Sigma_2 = 0.4 \cdot I_2$ , with  $y = \sin(x_1 + x_2) + \varepsilon$ , where error  $\varepsilon$  has a standard normal distribution. We choose these parameters of Gaussian mixture to make sure, that the probability of the vector  $X$  to be in the square  $[-2, 2]^2$  is close to 1.

We chose 100 Gaussian kernels as basis functions:

$$\psi_{i,j}(x) = \nabla \exp \left\{ - \frac{\|X - X_{i,j}\|^2}{2\sigma^2} \right\}, 1 \leq i, j \leq 10,$$

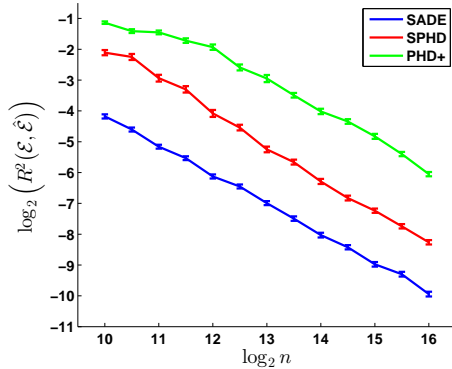

Figure 3: Mean and standard deviation of  $R^2(\mathcal{E}, \hat{\mathcal{E}})$  divided by 10 for the rational function (5.2) with  $\sigma = 1/4$

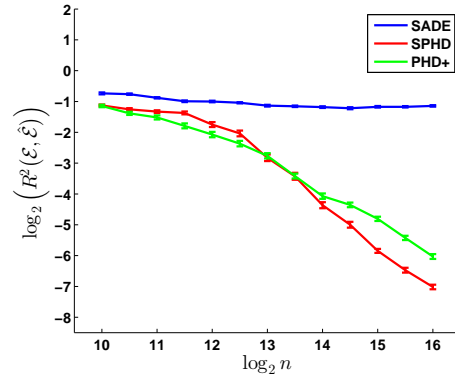

Figure 4: Mean and standard deviation of  $R^2(\mathcal{E}, \hat{\mathcal{E}})$  divided by 10 for the the classification problem (5.3)

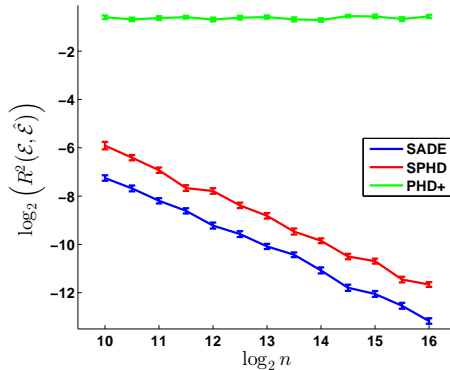

Figure 5: Mean and standard deviation of  $R^2(\mathcal{E}, \hat{\mathcal{E}})$  divided by 10 for the linear model (5.4)

where  $X_{i,j}$  form the uniform grid on the square  $[-2, 2]^2$  (note that this does not imply any notion of Gaussianity for the underlying density, and the Gaussian kernel here could be replaced by any differentiable local function).

In practice,  $\hat{\Psi}$  in (4.1) is close to be degenerated, and we use a regularized estimator  $\theta^* = -(\hat{\Psi} + \alpha I_T)^{-1} \cdot \hat{\Phi}$  instead.

We choose  $\alpha = 0.01$ ,  $\sigma = 1$  and conduct 100 replicates with numbers of observations  $n$  from  $2^{10}$  to  $2^{16}$  equally spaced in logarithmic scale. The results of the experiments are presented in Figure 6: the square trace error tends to zero as  $n$  increases.

In high dimensions, we can not use a uniform grid because of the curse of dimensionality. Instead of this, we will use  $n$  Gaussian kernels, centered in the sample points  $X_i$ . Note here that we can only recover an approximate score function, but our goal is the estimation of the e.d.r. subspace.

We use our reweighted least-squares algorithm to solve the convex problem (4.4). We conduct several experiments on functions

$$d = 10; \quad y = x_1(x_1 + x_2 - 3) + \varepsilon. \quad (5.5)$$

We plot the performance as a function of the kernel bandwidth  $\sigma$  to assess the robustness of the methods. On Figure 7 we provide the relationship between the square trace error and  $\sigma$  for quadratic model (5.5) for  $d = 10$  and  $n = 1000$ . In Figures 8, 9, 10, we provide the relationship between the

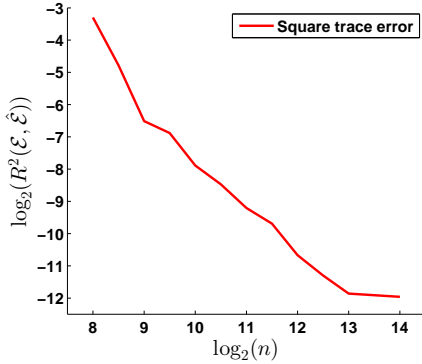

Figure 6: Square trace error  $R(\mathcal{E}, \hat{\mathcal{E}})$  for different sample sizes.

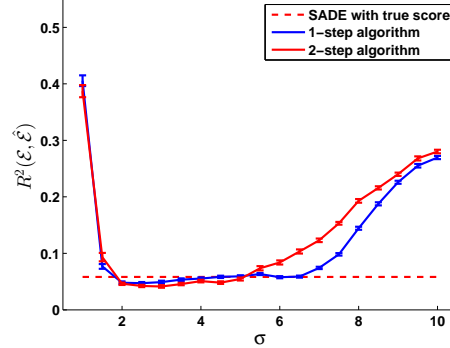

Figure 7: Quadratic model,  $d = 10, n = 1000$ .

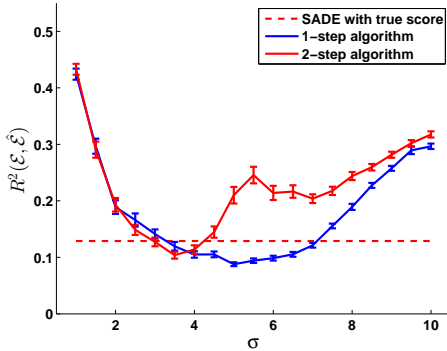

Figure 8: Rational model,  $d = 10, n = 1000$ .

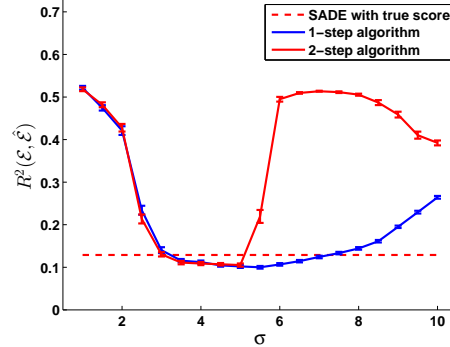

Figure 9: Rational model,  $d = 20, n = 2000$ .

square trace error and  $\sigma$  for rational model (5.2) for  $d = 10, n = 1000$ ;  $d = 20, n = 2000$  and  $d = 50, n = 5000$ . We see that for large  $d$ , the one-step algorithm is more robust than the two-step algorithm. Moreover, the experiments show that even with weak score functions, correct estimation of the e.d.r. space can be performed.

## 6 Conclusion

In this paper we consider a general non-linear regression model and the dependence on a unknown  $k$ -dimensional subspace assumption. Our goal was direct estimation of this unknown  $k$ -dimensional space, which is often called the effective dimension reduction or e.d.r. space. We proposed new approaches (SADE and SPHD), combining two existing techniques (sliced inverse regression (SIR) and score function-based estimation). We obtained consistent estimation for  $k > 1$  only using the first-order score and proposed explicit approaches to learn the score from data.

It would be interesting to extend our sliced extensions to learning neural networks: indeed, our work focused on the subspace spanned by  $w$  and cannot identify individual columns, while [18] showed that by using proper tensor decomposition algorithms and second-order score functions, columns of  $w$  can be consistently estimated (in polynomial time).

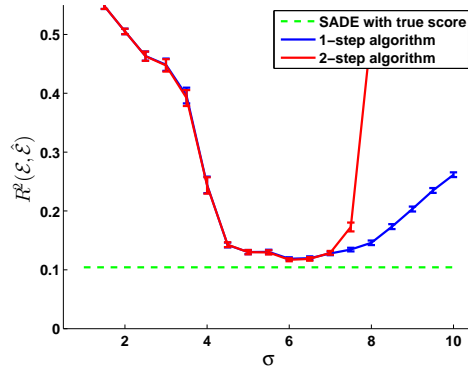

Figure 10: Rational model,  $d = 50$ ,  $n = 5000$ .

## Acknowledgements

The research leading to these results has received funding from the European Union’s H2020 Framework Programme (H2020-MSCA-ITN-2014) under grant agreement n° 642685 MacSeNet. We would like to thank Anastasia Podosinnikova and Anatoli Juditsky for interesting discussions related to this work.

## A Appendix. Proofs

In this appendix, we provide proofs which were omitted in the main paper.

### A.1 Probabilistic lemma

Let us first formulate and proof an auxiliary lemma about tail inequalities:

**Lemma 5.** *Let  $X$  be a non-negative random variable such that for some positive constants  $A$  and  $B$ , and all  $p$ :*

$$\mathbb{E}X^p \leq (A\sqrt{p} + Bn^{1/p}p^2)^p.$$

Then, for  $t \geq (\log n)/2$ :

$$\mathbb{P}(X \geq 3A\sqrt{t} + 3Bn^{1/t}t^2) \leq 3e^{-t}.$$

*Proof.* By Markov's inequality, for every non-negative integer  $p$ :

$$\begin{aligned} \mathbb{P}(X \geq 3A\sqrt{p} + 3Bn^{1/p}p^2) &= \mathbb{P}(X^p \geq [3A\sqrt{p} + 3Bn^{1/p}p^2]^p) \leq \\ &\leq \frac{[\mathbb{E}X^p]^p}{[3A\sqrt{p} + 3Bn^{1/p}p^2]^p} \leq e^{-p}. \end{aligned}$$

Consider any  $t > (\log n)/2$  and  $p = \lceil t \rceil$ , then:

$$\mathbb{P}(X \geq 3A\sqrt{t} + 3Bn^{1/t}t^2) \leq \mathbb{P}(X \geq 3A\sqrt{p} + 3Bn^{1/p}p^2) \leq e^{-p} \leq 3e^{-t},$$

because function  $f(t) = 3A\sqrt{t} + 3Bn^{1/t}t^2$  increases on  $[(\log n)/2; +\infty)$ .  $\square$

### A.2 Proof of theorem 1

*Proof.* Introduce notations:  $\ell_{(h,1)} = \ell(x_{(2h-1)})$ ,  $\ell_{(h,2)} = \ell(x_{(2h)})$ ,  $y_{(h,1)} = y_{(2h-1)}$  and  $y_{(h,2)} = y_{(2h)}$ . We have then, for  $c = 2$ , and  $H = n/c = n/2$ :

$$\hat{\mathcal{V}}_1 = \frac{1}{n} \sum_{h=1}^H (\ell_{(h,1)} - \ell_{(h,2)}) (\ell_{(h,1)} - \ell_{(h,2)})^\top,$$

Thus, the deviation from the population version, may be split into four terms as follows:

$$\begin{aligned} \hat{\mathcal{V}}_1 - \mathcal{V}_1 &= \frac{1}{n} \sum_{h=1}^H (\ell_{(h,1)} - \ell_{(h,2)}) (\ell_{(h,1)} - \ell_{(h,2)})^\top - \mathbb{E}\eta\eta^\top \\ &= \frac{1}{n} \sum_{h=1}^H (\eta_{(h,1)} - \eta_{(h,2)}) (\eta_{(h,1)} - \eta_{(h,2)})^\top - \mathbb{E}\eta\eta^\top \\ &\quad + \frac{1}{n} \sum_{h=1}^H (m(y_{(h,1)}) - m(y_{(h,2)})) (\eta_{(h,1)} - \eta_{(h,2)})^\top \\ &\quad + \frac{1}{n} \sum_{h=1}^H (\eta_{(h,1)} - \eta_{(h,2)}) (m(y_{(h,1)}) - m(y_{(h,2)}))^\top \\ &\quad + \frac{1}{n} \sum_{h=1}^H (m(y_{(h,1)}) - m(y_{(h,2)})) (m(y_{(h,1)}) - m(y_{(h,2)}))^\top \\ &= T_4 + T_3 + T_2 + T_1. \end{aligned}$$

We now bound each term separately.

**Bounding  $T_1$ .** We have

$$\begin{aligned} T_1 &\preceq \frac{1}{n} \sum_{h=1}^H L^2 (y_{(h,1)} - y_{(h,2)})(y_{(h,1)} - y_{(h,2)})^\top \\ \text{tr} T_1 = \|T_1\|_* &\leq \frac{1}{n} \sum_{h=1}^H L^2 \cdot \text{diameter}(y_1, \dots, y_n) |y_{(h,1)} - y_{(h,2)}| \\ &\leq \frac{1}{n} L^2 \cdot \text{diameter}(y_1, \dots, y_n)^2. \end{aligned}$$

The range cannot grow too much, i.e., as  $\log n$ . Indeed, assuming without loss of generality that  $\mathbb{E}y = 0$ , we have  $\max\{y_1, \dots, y_n\} \leq u/2$  and  $\min\{y_1, \dots, y_n\} \geq -u/2$  implies that the range is less than  $u$ , and thus,  $\mathbb{P}(\text{diameter}(y_1, \dots, y_n) \geq u) \leq \mathbb{P}(\max\{y_1, \dots, y_n\} \geq u/2) + \mathbb{P}(\min\{y_1, \dots, y_n\} \leq -u/2) \leq n\mathbb{P}(y > u/2) + n\mathbb{P}(y < -u/2) \leq 2n \exp(-u^2/8\tau_y^2)$  by using sub-Gaussianity. Then, by selecting  $u^2/8\tau_y^2 = \log(2n) + \log(8/\delta)$ , with get with probability greater than  $1 - \delta/8$  that  $\text{diameter}(y_1, \dots, y_n) \leq 2\sqrt{2}\tau_y \sqrt{\log(2n) + \log(8/\delta)}$ .

**Bounding  $T_2$  and  $T_3$ .** We also have

$$\begin{aligned} \max\{\|T_2\|_*, \|T_3\|_*\} &\leq \frac{1}{n} \sum_{h=1}^H L |y_{(h,1)} y_{(h,2)}| \cdot \text{diameter}(\eta_1, \dots, \eta_n) \\ &\leq \frac{1}{n} L \cdot \text{diameter}(y_1, \dots, y_n) \cdot \text{diameter}(\eta_1, \dots, \eta_n). \end{aligned}$$

Like for  $T_1$ , the ranges cannot grow too much, i.e., as  $\log n$ . Similarly  $\mathbb{P}(\text{diameter}((\eta_j)_1, \dots, (\eta_j)_n) \geq u) \leq n\mathbb{P}((\eta_j) > u/2) + n\mathbb{P}((\eta_j) < -u/2) \leq 2n \exp(-u^2/8\tau_\eta^2)$ . We thus with get with probability greater than  $1 - \delta/(8d)$  that  $\max_{j \in \{1, \dots, d\}} \text{diameter}((\eta_j)_1, \dots, (\eta_j)_n) \leq 2\sqrt{2}\tau_\eta \sqrt{\log(2n) + \log(8d/\delta)}$ .

Thus combining the two terms above, with probability greater than  $1 - \delta/4$ ,

$$\|T_1\|_* + \|T_2\|_* + \|T_3\|_* \leq \frac{8L(L\tau_y^2 + 2\tau_\eta\tau_y\sqrt{d})}{n} (\log(2n) + \log(8d) + \log(1/\delta)).$$

Note the term in  $\sqrt{d}$ , which corresponds to the definition of the diameter  $\text{diameter}(\eta_1, \dots, \eta_n)$  in terms of the  $\ell_2$ -norm.

**Bounding  $T_4$ .** We have:

$$\begin{aligned} T_4 &= \frac{1}{n} \sum_{h=1}^H \{ \eta_{(h,1)} \eta_{(h,1)}^\top + \eta_{(h,2)} \eta_{(h,2)}^\top - \eta_{(h,2)} \eta_{(h,1)}^\top - \eta_{(h,1)} \eta_{(h,2)}^\top \} - \mathbb{E} \eta \eta^\top \\ &= \frac{1}{n} \sum_{h=1}^H \{ -\eta_{(h,2)} \eta_{(h,1)}^\top - \eta_{(h,1)} \eta_{(h,2)}^\top \} + \frac{1}{n} \sum_{i=1}^n \eta_i \eta_i^\top - \mathbb{E} \eta \eta^\top = T_{4,1} + T_{4,2}. \end{aligned}$$

For the second term  $T_{4,2}$  above, if we select any element indexed by  $a, b$ , then

$$\frac{1}{n} \sum_{i=1}^n (\eta_i)_a (\eta_i)_b - \mathbb{E} \eta_a \eta_b.$$

Using [5, Theorem 2.1], we get

$$\mathbb{E}[(\eta_i)_a (\eta_i)_b]^2 \leq \sqrt{\mathbb{E}(\eta_i)_a^4 \mathbb{E}(\eta_i)_b^4} \leq 4(2\tau_\eta^2)^2 = 16\tau_\eta^4,$$

and

$$\mathbb{E}[|(\eta_i)_a \eta_i)_b|^q] \leq \sqrt{\mathbb{E}(\eta_i)_a^{2q} \mathbb{E}(\eta_i)_b^{2q}} \leq 2q!(2\tau_\eta^2)^q = \frac{q!}{2}(2\tau_\eta^2)^{q-2} 16\tau_\eta^4$$

We can then use Bernstein's inequality [5, Theorem 2.10], to get that with probability less than  $e^{-t}$  then

$$\frac{1}{n} \sum_{i=1}^n (\eta_i)_a (\eta_i)_b - \mathbb{E}\eta_a \eta_b \geq 2 \frac{\tau_\eta^2}{n} t + \sqrt{32\tau_\eta^4} \sqrt{t}/\sqrt{n}$$

Thus, with  $t = \log \frac{8d^2}{\delta}$ , we get that all  $d(d+1)/2$  absolute deviations are less than  $2\tau_\eta^2 \left( \frac{\log \frac{8d^2}{\delta}}{n} + \sqrt{\frac{2 \log \frac{8d^2}{\delta}}{n}} \right)$ , with probability greater than  $1 - \delta/4$ . This implies that the nuclear norm of the second term is less than  $2d\tau_\eta^2 \left( \frac{\log \frac{8d^2}{\delta}}{n} + \sqrt{\frac{2 \log \frac{8d^2}{\delta}}{n}} \right)$ , because for any matrix  $K \in \mathbb{R}^{d \times d}$ :  $\|K\|_* \leq d\|K\|_\infty$ .

For the first term, we consider  $Z = \sum_{h=1}^H (\eta_{(h,2)})_a (\eta_{(h,1)})_b$ , and consider conditioning on  $\mathbf{Y} = (y_1, \dots, y_n)$ . A key result from the theory of order statistics is that the  $n$  random variables  $\eta_{(h,2)}$ ,  $\eta_{(h,1)}$ ,  $h \in \{1, \dots, n/2\}$  are independent given  $\mathbf{Y}$  [27]. This allows us to compute expectations.

Using Rosenthal's inequality [5, Theorem 15.11] conditioned on  $\mathbf{Y}$ , for which we have  $\mathbb{E}((\eta_{(h,2)})_a (\eta_{(h,1)})_b | \mathbf{Y}) = 0$ , we get:

$$\begin{aligned} & [\mathbb{E}(|Z|^p | \mathbf{Y})]^{1/p} \leq \\ & \leq \sqrt{8p} \left[ \sum_h \mathbb{E} [((\eta_{(h,2)})_a (\eta_{(h,1)})_b)^2 | \mathbf{Y}] \right]^{1/2} + p \cdot 2 \left[ \mathbb{E} \max_h [((\eta_{(h,2)})_a (\eta_{(h,1)})_b)^p | \mathbf{Y}] \right]^{1/p} \\ & \leq \sqrt{8p} \left[ \sum_h \mathbb{E} [((\eta_{(h,2)})_a (\eta_{(h,1)})_b)^2 | \mathbf{Y}] \right]^{1/2} + p \cdot 2 \left[ \sum_h \mathbb{E} [((\eta_{(h,2)})_a (\eta_{(h,1)})_b)^p | \mathbf{Y}] \right]^{1/p}. \end{aligned}$$

By taking the  $p$ -th power, we get:

$$\begin{aligned} \mathbb{E}(|Z|^p | \mathbf{Y}) & \leq 2^{p-1} \sqrt{8p}^p \left[ \sum_h \mathbb{E} [((\eta_{(h,2)})_a (\eta_{(h,1)})_b)^2 | \mathbf{Y}] \right]^{p/2} \\ & \quad + 2^{p-1} p^p \cdot 2^p \sum_h \mathbb{E} [((\eta_{(h,2)})_a (\eta_{(h,1)})_b)^p | \mathbf{Y}]. \end{aligned}$$

By now taking expectations with respect to  $\mathbf{Y}$ , we get, using Jensen's inequality:

$$\begin{aligned} \mathbb{E}|Z|^p & \leq 2^{p-1} \sqrt{8p}^p \mathbb{E} \left( \left[ \sum_h (\eta_{(h,2)})_a^2 (\eta_{(h,1)})_b^2 \right]^{p/2} \right) \\ & \quad + 2^{p-1} p^p \cdot 2^p \sum_h \mathbb{E} [((\eta_{(h,2)})_a (\eta_{(h,1)})_b)^p] \\ & \leq 2^{p-1} \sqrt{8p}^p \mathbb{E} \left( \left[ \frac{1}{2} \sum_h (\eta_{(h,2)})_a^4 + (\eta_{(h,1)})_b^4 \right]^{p/2} \right) \\ & \quad + 2^{p-1} p^p \cdot 2^p \cdot \frac{1}{2} \sum_h \mathbb{E} [((\eta_{(h,2)})_a^{2p} + (\eta_{(h,1)})_b^{2p})] \\ & \leq 2^{p-1} \sqrt{8p}^p \mathbb{E} \left( \left[ \sum_i (\eta_i)_a^4 + (\eta_i)_b^4 \right]^{p/2} \right) \\ & \quad + 2^{p-1} p^p \cdot 2^p \sum_i \mathbb{E} [((\eta_i)_a^{2p} + (\eta_i)_b^{2p})] \end{aligned}$$

Because summing over all order statistics is equivalent to summing over all elements. Thus, using the bound on moments of  $(\eta_i)_b^2$ , we get:

$$\begin{aligned}\mathbb{E}|Z|^p &\leq 2^{p-1}\sqrt{8p^p}2^{p/2-1}\mathbb{E}\left([\sum_i(\eta_i)_a^4]^{p/2}\right) \\ &\quad + 2^{p-1}\sqrt{8p^p}2^{p/2-1}\mathbb{E}\left([\sum_i(\eta_i)_b^4]^{p/2}\right) + 2^{p-1}p^p \cdot 2^p n \cdot 4p!(2\tau_\eta^2)^p\end{aligned}$$

We can now use [5, Theorem 15.10], to get

$$\begin{aligned}\left[\mathbb{E}\left([\sum_i(\eta_i)_a^4]^{p/2}\right)\right]^{2/p} &\leq 2\mathbb{E}\left[\sum_i(\eta_i)_a^4\right] + \frac{p}{2}\left(\mathbb{E}\left[\max_i((\eta_i)_a^4)^{p/2}\right]\right)^{2/p} \\ &\leq 2\mathbb{E}\left[\sum_i(\eta_i)_a^4\right] + \frac{p}{2}\left(\mathbb{E}\left[\sum_i((\eta_i)_a^4)^{p/2}\right]\right)^{2/p} \\ &\leq 2n \times 4(2\tau_\eta^2)^2 + \frac{p}{2}n^{2/p}\mathbb{E}\eta_i^{2p} \\ &\leq (32n + n^{2/p}\frac{p}{2}(2p!)^{2/p})\tau_\eta^4 \\ &\leq (32n + n^{2/p}p^3)\tau_\eta^4\end{aligned}$$

Thus

$$\begin{aligned}\mathbb{E}|Z|^p &\leq 2^p\sqrt{8p^p}2^{p/2-1}(32n + n^{2/p}p^3)^{p/2}\tau_\eta^{2p} + 2^{p-1}p^p \cdot 2^p n \cdot 4p!(2\tau_\eta^2)^p \\ &\leq 2^{3p-1}p^{p/2} \cdot 2^{p/2-1}((32n)^{p/2} + n \cdot p^{3p/2})\tau_\eta^{2p} + 2^{3p+1}\tau_\eta^{2p}np^{2p} \\ &\leq (2^{6p-2}p^{p/2}n^{p/2} + np^{2p}[2^{7p/2-2} + 2^{3p+1}])\tau_\eta^{2p} \\ &\leq (64^p \cdot p^{p/2}n^{p/2} + 19^p \cdot np^{2p})\tau_\eta^{2p}\end{aligned}$$

Thus

$$(\mathbb{E}|Z|^p)^{1/p} \leq (64 \cdot \sqrt{p}n^{1/2} + 19 \cdot n^{1/p}p^2)\tau_\eta^2.$$

Thus, for any  $\delta \leq 1/n$ , using Lemma 5 for random variable  $Z/n$  with  $t = \log(\frac{12d^2}{\delta}) > (\log n)/2$  and we obtain:

$$\begin{aligned}\mathbb{P}\left[\left|\frac{Z}{n}\right| \geq \frac{192\tau_\eta^2}{\sqrt{n}}\sqrt{t} + \frac{57\tau_\eta^2}{n}n^{1/t}t^2\right] &\leq 3e^{-t} \Rightarrow \\ \mathbb{P}\left[\left|\frac{Z}{n}\right| \geq \frac{192\tau_\eta^2}{\sqrt{n}}\sqrt{\log(\frac{12d^2}{\delta})} + \frac{57\tau_\eta^2}{n}n^{1/\log(\frac{12d^2}{\delta})}\log^2(\frac{12d^2}{\delta})\right] &\leq \frac{\delta}{4d^2} \Rightarrow \\ \mathbb{P}\left[\left|\frac{Z}{n}\right| \geq \frac{192\tau_\eta^2}{\sqrt{n}}\sqrt{\log(\frac{12d^2}{\delta})} + \frac{155\tau_\eta^2}{n}\log^2(\frac{12d^2}{\delta})\right] &\leq \frac{\delta}{4d^2}.\end{aligned}$$

Combining all terms  $T_1, T_2, T_3, T_{4,1}$  and  $T_{4,2}$  we get with probability not less than  $1 - \delta$ :

$$\begin{aligned}\|\hat{\mathcal{V}}_1 - \mathcal{V}_1\|_* &\leq \frac{1}{n} \cdot \left[8L(L\tau_y^2 + 2\tau_\eta\tau_y\sqrt{d}) \cdot \log(\frac{16dn}{\delta}) + 2d\tau_\eta^2 \log \frac{8d^2}{\delta} + 155\tau_\eta^2 d \log^2(\frac{12d^2}{\delta})\right] \\ &\quad + \frac{1}{\sqrt{n}} \left[2d\tau_\eta^2 \sqrt{2 \log \frac{8d^2}{\delta}} + 192\tau_\eta^2 d \sqrt{\log \frac{12d^2}{\delta}}\right].\end{aligned}$$

Finally, rearranging terms, with probability not less, than  $1 - \delta$ :

$$\|\hat{\mathcal{V}}_1 - \mathcal{V}_1\|_* \leq \frac{195d\tau_\eta^2}{\sqrt{n}}\sqrt{\log \frac{12d^2}{\delta}} + \frac{8L^2\tau_y^2 + 16\tau_\eta\tau_yL\sqrt{d} + 157\tau_\eta^2 d}{n} \log^2 \frac{16d^2 n}{\delta}.$$

□

### A.3 Proof of Theorem 2

*Proof.* Using triangle inequality, we get:

$$\|\mathcal{V}_1(\theta^*) - \hat{\mathcal{V}}_1(\hat{\theta})\|_* \leq \|\mathcal{V}_1(\theta^*) - \hat{\mathcal{V}}_1(\theta^*)\|_* + \|\hat{\mathcal{V}}_1(\theta^*) - \hat{\mathcal{V}}_1(\hat{\theta})\|_* = \mathcal{F}_1 + \mathcal{F}_2. \quad (\text{A.1})$$

Theorem 1 supplies us with non-asymptotic analysis for the  $\mathcal{F}_1$  term: with probability not less than  $1 - \delta/2$ :

$$\begin{aligned} & \|\mathcal{V}_1(\theta^*) - \hat{\mathcal{V}}_1(\theta^*)\|_* \leq \\ & \frac{195d\tau_\eta^2}{\sqrt{n}} \sqrt{\log \frac{24d^2}{\delta}} + \frac{8L^2\tau_y^2 + 16\tau_\eta\tau_yL\sqrt{d} + 157\tau_\eta^2d}{n} \log^2 \frac{32d^2n}{\delta}. \end{aligned} \quad (\text{A.2})$$

For the second term, let us firstly analyse the norm  $\|\theta^* - \hat{\theta}\|$ . For simplicity, introduce notation:  $\hat{C} = \frac{1}{n} \sum_{i=1}^n \Psi(x_i)\Psi(x_i)^\top \in \mathbb{R}^{m \times m}$ ,  $C = \mathbb{E}[\Psi(x)\Psi(x)^\top] \in \mathbb{R}^{m \times m}$ ,  $\hat{b} = \frac{1}{n} \sum_{i=1}^n (\nabla \cdot \Psi)(x_i) \in \mathbb{R}^m$  and  $b = \mathbb{E}[(\nabla \cdot \Psi)(x)] \in \mathbb{R}^m$

Let us estimate  $\|\hat{C} - C\|_F$  and  $\|\hat{b} - b\|$ .

Introduce notation:

$$C_{a,b}^c = \frac{1}{n} \sum_{i=1}^n \Psi_c^a(x_i) \cdot \Psi_c^b(x_i) - \mathbb{E}[\Psi_c^a(x) \cdot \Psi_c^b(x)]$$

It can be shown like in the bounding of  $T_{4,2}$  term in the Theorem's 1 proof, using [5, Theorem 2.1] and Bernstein's inequality [5, Theorem 2.10] that with probability less than  $e^{-t}$ :

$$C_{a,b}^c \geq 2 \frac{\tau_\Psi^2}{n} t + \sqrt{32\tau_\Psi^4 \sqrt{t}/\sqrt{n}}.$$

Taking  $t = \log \frac{m^2d}{\delta}$  we show that:

$$\mathbb{P} \left[ \|\hat{C} - C\|_F \geq 2\tau_\Psi^2 \sqrt{m^3d} \left( \frac{\log \frac{m^2d}{\delta}}{n} + \sqrt{\frac{2 \log \frac{m^2d}{\delta}}{n}} \right) \right] < \delta.$$

According to assumption **(M2)** and Hoeffding bound:

$$\mathbb{P} \left[ \|\hat{b}_i - b_i\| \geq \frac{t}{n} \right] \leq e^{\frac{-t^2}{2\tau_\Psi^2 n}},$$

combining inequalities for all  $m$  components of  $b$ , we have:

$$\mathbb{P} \left[ \|b - \hat{b}\| \geq \frac{\tau_{\nabla \Psi} \sqrt{m}}{\sqrt{n}} \sqrt{\log \frac{m^2}{\delta^2}} \right] \leq \delta.$$

Now, let estimate  $\|\theta^* - \hat{\theta}\|$ :

$$\theta^* - \hat{\theta} = \hat{C}^{-1}\hat{b} - C^{-1}b = \hat{C}^{-1}(\hat{b} - b) + (\hat{C}^{-1} - C^{-1})b \Rightarrow$$

$$\|\theta^* - \hat{\theta}\| \leq \frac{\|\hat{b} - b\|}{\lambda_{\min}(\hat{C})} + \frac{\|b\|_2 \cdot \|C - \hat{C}\|_{\text{op}}}{\lambda_{\min}(C) \cdot \lambda_{\min}(\hat{C})}.$$

For  $n$  large enough (for some constants  $c_1$  and  $c_2$ , not depending on  $n$  and  $\delta$ :  $n > c_1 + c_2 \log \frac{1}{\delta}$ )  $\|\hat{C} - C\| \leq \frac{\lambda_{\min}}{2}$  with probability more, than  $1 - \delta/12$  hence for this  $n$ :  $\lambda_{\min}(\hat{C}) \geq \frac{\lambda_{\min}(C)}{2}$ , hence,

combining 3 estimations for  $\|\hat{b} - b\|$ ,  $\|\hat{C} - C\|$  and for  $\lambda_{\min}(\hat{C})$ , we obtain estimation for  $\|\theta^* - \hat{\theta}\|$ : with probability not less, than  $1 - \delta/4$ :

$$\|\theta^* - \hat{\theta}\| \leq \frac{2\tau_{\nabla\Psi}\sqrt{m}}{\sqrt{n}\lambda_{\min}(C)}\sqrt{2\log\frac{12m}{\delta}} + \frac{2\|b\|}{\lambda_{\min}^2(C)} \cdot 2\tau_{\Psi}^2\sqrt{m^3d}\left(\frac{\log\frac{12m^2d}{\delta}}{n} + \sqrt{\frac{2\log\frac{12m^2d}{\delta}}{n}}\right) \quad (\text{A.3})$$

Consider now  $(a, b)$  element of  $\hat{\mathcal{V}}_1(\theta^*) - \hat{\mathcal{V}}_1(\hat{\theta})$ :

$$\begin{aligned} \left[\hat{\mathcal{V}}_1(\theta^*) - \hat{\mathcal{V}}_1(\hat{\theta})\right]_{a,b} &= \sum_{h=1}^H \sum_{\alpha,\beta=1}^m \hat{p}_h [\hat{\Psi}_h]_a^\alpha [\hat{\Psi}_h]_b^\beta \cdot |\theta_\alpha^* \theta_\beta^* - \hat{\theta}_\alpha \hat{\theta}_\beta| = \\ &\sum_{h=1}^H \sum_{\alpha,\beta=1}^m \hat{p}_h \left[ \frac{1}{n\hat{p}_h} \sum_{i=1}^n [1_{y_i \in I_h} \cdot \Psi(x_i)_a^\alpha] \cdot \frac{1}{n\hat{p}_h} \sum_{j=1}^n [1_{y_j \in I_h} \cdot \Psi(x_j)_b^\beta] \right] \cdot |\theta_\alpha^* \theta_\beta^* - \hat{\theta}_\alpha \hat{\theta}_\beta| \leq \\ &\sum_{h=1}^H \sum_{\alpha,\beta=1}^m \frac{1}{n^2 \hat{p}_h} \cdot \frac{n\hat{p}_h}{2} \left[ \sum_{i=1}^n [1_{y_i \in I_h} \cdot \Psi(x_i)_a^\alpha]^2 + \sum_{j=1}^n [1_{y_j \in I_h} \cdot \Psi(x_j)_b^\beta]^2 \right] \cdot |\theta_\alpha^* \theta_\beta^* - \hat{\theta}_\alpha \hat{\theta}_\beta| \leq \\ &\sum_{\alpha,\beta=1}^m \frac{1}{2n} \left[ \sum_{i=1}^n [\Psi(x_i)_a^\alpha]^2 + \sum_{i=1}^n [\Psi(x_i)_b^\beta]^2 \right] \cdot |\theta_\alpha^* \theta_\beta^* - \hat{\theta}_\alpha \hat{\theta}_\beta|. \end{aligned}$$

Now, let us estimate desired norm:

$$\|\hat{\mathcal{V}}_1(\theta^*) - \hat{\mathcal{V}}_1(\hat{\theta})\|_* \leq m \cdot \sum_{k=1}^n \sum_{l=1}^d \frac{\sum_{i=1}^n |\Psi_l^k(x_i)|^2}{n} \cdot (2\|\theta^*\| + \|\hat{\theta} - \theta^*\|) \cdot \|\hat{\theta} - \theta^*\| \quad (\text{A.4})$$

Using again [5, Theorem 2.1] and Bernstein's inequality [5, Theorem 2.10] with probability not less than  $1 - \delta/8$ :

$$\sum_{k=1}^n \sum_{l=1}^d \frac{\sum_{i=1}^n |\Psi_l^k(x_i)|^2}{n} \leq \mathbb{E}\|\Psi(x)\|_2^2 + 2md\tau_\psi^2 \left( \frac{\log\frac{4md}{\delta}}{n} + \sqrt{\frac{2\log\frac{4md}{\delta}}{n}} \right) \quad (\text{A.5})$$

For  $n$  large enough (for some constants  $c_1$  and  $c_2$ , not depending on  $n$  and  $\delta$ :  $n > c_1 + c_2 \log \frac{1}{\delta}$ ):

$$\sum_{k=1}^n \sum_{l=1}^d \frac{\sum_{i=1}^n |\Psi_l^k(x_i)|^2}{n} \leq \frac{3}{2} \mathbb{E}\|\Psi(x)\|_2^2 \quad \text{with probability no less than } 1 - \delta/8$$

and

$$(2\|\theta^*\| + \|\hat{\theta} - \theta^*\|) \leq 3\|\theta^*\| \quad \text{with probability no less than } 1 - \delta/8$$

$$\|\hat{\mathcal{V}}_1(\theta^*) - \hat{\mathcal{V}}_1(\hat{\theta})\|_* \leq m \cdot \frac{9}{2} \mathbb{E}\|\Psi(x)\|_2^2 \cdot \|\theta^*\|.$$

$$\left[ \frac{2\tau_{\nabla\Psi}\sqrt{m}}{\sqrt{n}\lambda_{\min}(C)}\sqrt{2\log\frac{12m}{\delta}} + \frac{2\|b\|}{\lambda_{\min}^2(C)} \cdot 2\tau_{\Psi}^2\sqrt{m^3d}\left(\frac{\log\frac{12m^2d}{\delta}}{n} + \sqrt{\frac{2\log\frac{12m^2d}{\delta}}{n}}\right) \right]$$

with probability not less than  $1 - \delta/2$ .

Combining and simplifying obtained inequality and (A.2) we obtain final inequality: with probability not less, then  $1 - \delta$ :

$$\begin{aligned} & \|\mathcal{V}_1(\theta^*) - \hat{\mathcal{V}}_1(\hat{\theta})\|_* \leq \\ & \frac{1}{\sqrt{n}} \sqrt{2 \log \frac{12m^2d}{\delta}} \cdot \left[ 195d\tau_\eta^2 + \frac{9m}{2} \mathbb{E}\|\Psi(x)\|_2^2 \cdot \|\theta^*\| \left( \frac{2\tau_{\nabla\Psi}\sqrt{m}}{\lambda_{\min}(C)} + \frac{4\|b\|\tau_\Psi^2\sqrt{m^3d}}{\lambda_{\min}^2(C)} \right) \right] \\ & \quad + O\left(\frac{1}{n}\right). \end{aligned}$$

□
