Abstract

`imbalanced-learn` is an open-source python toolbox aiming at providing a wide range of methods to cope with the problem of imbalanced dataset frequently encountered in machine learning and pattern recognition. The implemented state-of-the-art methods can be categorized into 4 groups: (i) under-sampling, (ii) over-sampling, (iii) combination of over- and under-sampling, and (iv) ensemble learning methods. The proposed toolbox depends only on `numpy`, `scipy`, and `scikit-learn` and is distributed under MIT license. Furthermore, it is fully compatible with `scikit-learn` and is part of the `scikit-learn-contrib` supported project. Documentation, unit tests as well as integration tests are provided to ease usage and contribution. Source code, binaries, and documentation can be downloaded from `https://github.com/scikit-learn-contrib/imbalanced-learn`.

Keywords: Imbalanced Dataset, Over-Sampling, Under-Sampling, Ensemble Learning, Machine Learning, Python.

1. Introduction

Real world datasets commonly show the particularity to have a number of samples of a given class under-represented compared to other classes. This imbalance gives rise to the "class imbalance" problem (Prati et al., 2009) (or "curse of imbalanced datasets") which is the problem of learning a concept from the class that has a small number of samples.

The class imbalance problem has been encountered in multiple areas such as telecommunication managements, bioinformatics, fraud detection, and medical diagnosis, and has been considered one of the top 10 problems in data mining and pattern recognition (Yang and Wu, 2006; Rastgoo et al., 2016). Imbalanced data substantially compromises the learning process, since most of the standard machine learning algorithms expect balanced class distribution or an equal misclassification cost (He and Garcia, 2009). For this reason, several

approaches have been specifically proposed to handle such datasets. Some of these methods have been implemented mainly in R language (Torgo, 2010; Kuhn, 2015; Dal Pozzolo et al., 2013). Up to our knowledge, there is no python toolbox allowing such processing while cutting edge machine learning toolboxes are available (Pedregosa et al., 2011; Sonnenburg et al., 2010).

In this paper, we present the `imbalanced-learn` API, *a python toolbox to tackle the curse of imbalanced datasets in machine learning*. The following sections present the project vision, a snapshot of the API, an overview of the implemented methods, and finally, we conclude this work by including future functionalities for the `imbalanced-learn` API.

2. Project management

Quality assurance In order to ensure code quality, a set of unit tests is provided leading to a coverage of 99 % for the release 0.2 of the toolbox. Furthermore, the code consistency is ensured by following `PEP8` standards and each new contribution is automatically checked through landscape, which provides metrics related to code quality.
Continuous integration To allow both the user and the developer to either use or contribute to this toolbox, Travis CI is used to easily integrate new code and ensure back-compatibility.
Community-based development All the development is performed in a collaborative manner. Tools such as git, GitHub, and gitter are used to ease collaborative programming, issue tracking, code integration, and idea discussions.
Documentation A consistent API documentation is provided using `sphinx` and `numpydoc`. An additional installation guide and examples are also provided and centralized on GitHub[1].
Project relevance At the edition time, the repository is visited no less than 2,000 times per week, attracting about 300 unique visitors per week. Additionally, the toolbox is supported by `scikit-learn` through the `scikit-learn-contrib` projects.

3. Implementation design

```
from sklearn.datasets import make_classification
from sklearn.decomposition import PCA
from imblearn.over_sampling import SMOTE

# Generate the dataset
X, y = make_classification(n_classes=2, weights=[0.1, 0.9],
                           n_features=20, n_samples=5000)

# Apply the SMOTE over-sampling
sm = SMOTE(ratio='auto', kind='regular')
X_resampled, y_resampled = sm.fit_sample(X, y)
```

Listing 1: Code snippet to over-sample a dataset using SMOTE.

The implementation relies on `numpy`, `scipy`, and `scikit-learn`. Each sampler class implements three main methods inspired from the `scikit-learn` API: (i) `fit` computes several statistics which are later needed to resample the data into a balanced set; (ii)

SMOTE + ENN (Batista et al., 2003)	✓	✗	✓	✗
SMOTE + TL (Batista et al., 2003)	✓	✗	✓	✗

`sample` performs the sampling and returns the data with the desired balancing ratio; and (iii) `fit_sample` is equivalent to calling the method `fit` followed by the method `sample`. A class `Pipeline` is inherited from the `scikit-learn` toolbox to automatically combine `samplers`, `transformers`, and `estimators`. Additionally, we provide some specific state-of-the-art metrics to evaluate classification performance.

4. Implemented methods

The `imbalanced-learn` toolbox provides four different strategies to tackle the problem of imbalanced dataset: (i) under-sampling, (ii) over-sampling, (iii) a combination of both, and (iv) ensemble learning. The following subsections give an overview of the techniques implemented.

4.1 Notation and background

Let χ be an imbalanced dataset with χ_{min} and χ_{maj} being the subset of samples belonging to the minority and majority class, respectively. The balancing ratio of the dataset χ is defined as:

$$r_{\chi} = \frac{|\chi_{min}|}{|\chi_{maj}|} \ , \tag{1}$$

where $|\cdot|$ denotes the cardinality of a set. The balancing process is equivalent to resample χ into a new dataset χ_{res} such that $r_{\chi} > r_{\chi_{res}}$.

Under-sampling Under-sampling refers to the process of reducing the number of samples in χ_{maj}. The implemented methods can be categorized into 2 groups: (i) fixed under-sampling and (ii) cleaning under-sampling. *Fixed under-sampling* refer to the methods which perform under-sampling to obtain the appropriate balancing ratio $r_{\chi_{res}}$. Contrary to the previous methods, *cleaning under-sampling* do not allow to reach specifically the balancing ratio $r_{\chi_{res}}$, but rather clean the feature space based on some empirical criteria.

Over-sampling Contrary to under-sampling, data balancing can be performed by over-sampling such that new samples are generated in χ_{min} to reach the balancing ratio $r_{\chi_{res}}$.

Combination of over- and under-sampling Over-sampling can lead to over-fitting which can be avoided by applying cleaning under-sampling methods (Prati et al., 2009).

Ensemble learning Under-sampling methods imply that samples of the majority class are lost during the balancing procedure. Ensemble methods offer an alternative to use most of the samples. In fact, an ensemble of balanced sets is created and used to later train any classifier.

5. Future plans and conclusion

In this paper, we shortly presented the foundations of the `imbalanced-learn` toolbox vision and API. As avenues for future works, additional methods based on prototype/instance selection, generation, and reduction will be added as well as additional user guides.
