#### Abstract

We investigate, in the context of functional prototype-based languages, a calculus of objects which might extend themselves upon receiving a message, a capability referred to by Cardelli as a self-inflicted operation. We present a sound type system for this calculus which guarantees that evaluating a well-typed expression will never yield a message-not-found runtime error. The resulting calculus is an attempt towards the definition of a language combining the safety advantage of static type checking with the flexibility normally found in dynamically typed languages.

Keywords Prototype-based calculi, static typing, object reclassification

## 1 Introduction

Object calculi and languages can be divided in the two main categories of class-based and prototype-based (a.k.a. object-based) ones. The latter, whose best-known example is JavaScript, provide the programmer with a greater flexibility compared to those classed-based, e.g. the possibility of changing at runtime the behaviour of objects, by modifying or adding methods. Although such a flexibility is normally payed by the lack of static type systems, this is not necessarily the case, as it is possible to define a statically typed, prototype-based language. One example in this direction was the Lambda Calculus of Objects ( $\lambda \mathcal{O} b j$ ), introduced by Fisher, Honsell, and Mitchell [FHM94] as a first solid foundation for the prototyped-based paradigm.
$\lambda \mathcal{O} b j$ is a lambda calculus extended with object primitives, where a new object may be created by modifying or extending an existing prototype. The new object thereby inherits properties from the original one in a controlled manner. Objects can be viewed as lists of pairs (method name, method body) where the method body is (or reduces to) a lambda abstraction whose first formal parameter is always the object itself (this in $\mathrm{C}^{++}$and Java). The type assignment system of $\lambda \mathcal{O} b j$ is set up so as to prevent the unfortunate message-not-found runtime error. Types of methods are allowed to be specialized to the type of the inheriting objects. This feature is usually
referred to as "mytype method specialization". The high mutability of method bodies is accommodated in the type system via an implicit form of higher-order polymorphism, inspired by the the work of Wand on extensible records [Wan87].

The calculus $\lambda \mathcal{O} b j$ spurred an intense research in type assignment systems for object calculi. Several calculi inspired by $\lambda \mathcal{O} b j$, dealing with various extra features such as incomplete objects, subtyping, encapsulation, imperative features, have appeared soon afterwards (see e.g. [FM95, BL95, BBDL97, FM98, BF98]).

More specifically, $\lambda \mathcal{O} b j$ supports two operations which may change the shape of an object: method addition and method override. The operational semantics of the calculus allows method bodies in objects to modify their own self, a powerful capability referred to by Cardelli as a self-inflicted operation [Car95].

Consider the method $\operatorname{set}_{x}$ belonging, among others, to a $p t$ object with an $x$ field:

$$
p t \triangleq\left\langle x=\lambda s .0, \operatorname{set}_{x}=\lambda s . \lambda v .\left\langle s \leftarrow x=\lambda s^{\prime} . v\right\rangle, \ldots\right\rangle
$$

When $\operatorname{set}_{x}$ is called to $p t$ with argument " 3 ", written as $p t \Leftarrow \operatorname{set}_{x}(3)$, the result is a new object where the $x$ field has been set (i.e. overridden) to 3 . Notice the self-inflicted operation of object override (i.e. $\leftarrow$ ) performed by the set ${ }_{x}$ method.

However, in all the type systems for calculi of objects, both those derived from $\lambda \mathcal{O} b j$ and those derived from Abadi and Cardelli's foundational Object Calculus [AC96], the type system prevents the possibility for a method to self-inflict an extension to the host object. We feel that this is an unpleasant limitation if the message-passing paradigm is to be taken in full generality. Moreover, in $\lambda \mathcal{O} b j$ this limitation appears arbitrary, given that the operational semantics supports without difficulty self-inflicted extension methods.

There are plenty of situations, both in programming and in real life, where it would be convenient to have objects which modify their interface upon an execution of a message. Consider for instance the following situations.

- The process of learning could be easily modeled using an object which can react to the "teacher's message" by extending its capability of performing, in the future, a new task in response to a new request from the environment (an old dog could appear to learn new tricks if in his youth it had been taught a "self-extension" trick).
- The process of "vaccination" against the virus $\mathcal{X}$ can be viewed as the act of extending the capability of the immune system of producing, in the future, a new kind of " $\mathcal{X}$-antibodies" upon receiving the message that an $\mathcal{X}$-infection is in progress. Similar processes arise in epigenetics.
- In standard typed class-based languages the structure of a class can be modified only statically. If we need to add a new method to an instance of a class we are forced to recompile the class and to make the modification needlessly available to all the class instances, thereby wasting memory. If a class had a self-extension method, only the instances of the class which have dynamically executed this method would allocate new memory, without the need of any re-compilation. As a consequence, many sub-class declarations could be easily explained away if suitable self-extension methods in the parent class were available.
- Downcasting could be smoothly implementable on objects with self-extension methods. For example, for a colored point cpt extending the pt object above,
the following expression could be made to type check (details in Section 5):

$$
c p t \Leftarrow e q\left(p t \Leftarrow a d d_{c o l}(b l a c k)\right)
$$

where $a d d_{c o l}$ is intended to be a self-extension method of $p t$ (adding a col method) and $e q$ is the name of the standard binary equality method.

- Self-extension is strictly related to object evolution and object reclassification (see Sections 7 and 8), two features which are required in areas such as e.g. banking, GUI development, and games.

Actually, the possibility of modifying objects at runtime is already available in dynamically typed languages such as Smalltalk (via the become method), Python (by modifying the _class_ attribute), and Ruby. On the other hand, the self-extension itself is present, and used, in the prototype-based JavaScript language.

In such a scenario, the goal of this paper is to introduce the prototype-based $\lambda \mathcal{O} b j^{\oplus}$, a lambda calculus of objects in the style of $\lambda \mathcal{O} b j$, together with a type assignment system which allows self-inflicted extension still catching statically the message-notfound runtime error. This system can be further extended to accommodate other subtyping features; by way of example we will present a "width-subtyping" relation that permits sound method override and a limited form of object extension. In fact, this manuscript completes and extends the paper [DGHL98].

We remark that the research presented in this article belongs to a series of similar investigations [Zha10, CHJ12, Zha12], whose aim is to define more and more powerful type assignment systems, capable to statically type check larger and larger fragments of a prototype-based, dynamically typed language like JavaScript. The ultimate goal is the definition of a language combining the safety advantage of static type checking with the flexibility normally found in dynamically typed languages.

## Self-inflicted extension

To enable the $\lambda \mathcal{O} b j^{\oplus}$ calculus to perform self-inflicted extensions, two modifications of the system in [FHM94] are necessary. The first is, in effect, a simplification of the original syntax of the language. The second is much more substantial and it involves the type discipline.

As far as the syntax of the language is concerned, we are forced to unify into a single operator, denoted by $\oplus$, the two original object operators of $\lambda \mathcal{O b j}$, i.e. object extension $(\leftarrow)$ and object override $(\leftarrow)$. This is due to the fact that, when iterating the execution of a self-extension method, only the first time we have a genuine object extension, while from the second time on we have just a simple object override.

Example 1.1 Consider the add $d_{\text {col }}$ method, that adds a col field to the "point" object p:

$$
p \triangleq\left\langle x=\lambda s .0, s e t_{x}=\lambda s \cdot \lambda v \cdot\left\langle s \leftarrow x=\lambda s^{\prime} \cdot v\right\rangle, a d d_{c o l}=\lambda s \cdot \lambda v \cdot\left\langle s \leftrightarrow \oplus c o l=\lambda s^{\prime} \cdot v\right\rangle\right\rangle
$$

When add $d_{\text {col }}$ is sent to $p$ with argument "white", i.e. $p \Leftarrow a d d_{c o l}(w h i t e)$, the result is a new object cp where the col field has been added to $p$ and set to white:

$$
c p \triangleq\left\langle x=\ldots, \text { set }_{x}=\ldots, a d d_{c o l}=\ldots, \text { col }=\lambda \text { s.white }\right\rangle
$$

If $a d d_{\text {col }}$ is sent twice to $p$, i.e. $c p \Leftarrow a d d_{\text {col }}($ black $)$, then, since the col field is already present in cp, it will be overridden with the new "black" value:

$$
c p^{\prime} \triangleq\left\langle x=\ldots, \operatorname{set}_{x}=\ldots, a d d_{c o l}=\ldots, \text { col }=\lambda s . w h i t e, c o l=\lambda s . b l a c k\right\rangle
$$

Therefore, only the rightmost version of a method will be the effective one.

As far as types are concerned, we add two new kinds of object-types, namely $\tau \oplus m$, which can be seen as the type theoretical counterpart of the syntactic object $\left\langle e_{1} \oplus m=e_{2}\right\rangle$, and prot. $R \oplus m_{1} \ldots \oplus m_{k}$, a generalization of the original classt. $R$ in [FHM94], named pro-type. Intuitively, if the type prot. $R \oplus m_{1} \ldots \oplus m_{k}$ is assigned to an object $e\left(t\right.$ represents the type of self), $e$ can respond to all the methods $m_{1}, \ldots, m_{k}$. Mandatory, the list of pairs $R$ contains all the methods $m_{1}, \ldots, m_{k}$ together with their corresponding types; moreover, $R$ may contain some reserved methods, i.e. methods that can be added to $e$ either by ordinary object-extension or by a method in $R$ which performs a self-inflicted extension (therefore, if $R$ did not contain reserved methods, prot. $R \oplus m_{1} \ldots \oplus m_{k}$ would coincide with classt.R of [FHM94]).

To convey to the reader the intended meaning of pro-types, let us suppose that an object $e$ is assigned the type prot. $\langle m: t \oplus n, n: i n t\rangle \oplus m$. In fact, $e \Leftarrow n$ is not typable, but as $e \Leftarrow m$ has the effect of adding the method $n$ to the interface of $e$, thus updating the type of $e$ to prot. $\langle m: t \oplus n, n: i n t\rangle \oplus m \oplus n$, then $(e \Leftarrow m) \Leftarrow n$ is typable.

The list of reserved methods in a pro-type is crucial to enforce the soundness of the type assignment system. Consider e.g. an object containing two methods, $a d d n_{1}$, and $a d d n_{2}$, each of them self-inflicting the extension of a new method $n$. The type assignment system has to carry enough information so as to enforce that the same type will be assigned to $n$ whatever self-inflicted extension has been executed.

The typing system that we will introduce ensures that we can always dynamically add new fresh methods for pro-types, thus leaving intact the original philosophy of rapid prototyping, peculiar to object calculi.

To model specialization of inherited methods, we use the notion of matching, a.k.a. type extension, originally introduced by Bruce [Bru94] and later applied to the Object Calculus [AC96] and to $\lambda \mathcal{O} b j$ [BB99]. At the price of a little more mathematical overhead, we could have used also the implicit higher-order polymorphism of [FHM94].

## Object subsumption.

As it is well-known, see e.g. [AC96, FM94], the introduction of a subsumption relation over object-types makes the type system unsound. In particular, width-subtyping clashes with object extension, and depth-subtyping clashes with object override. In fact, on pro-types no subtyping is possible. In order to accommodate subtyping, we add another kind of object-type, i.e. objt. $R \oplus m_{1} \ldots \oplus m_{k}$, which behaves like prot. $R \oplus m_{1} \ldots \oplus m_{k}$ except that it can be assigned to objects which can be extended only by making longer the list $\oplus m_{1} \ldots \oplus m_{k}$ (by means of reserved methods that appear in $R$ ). On obj-types a (covariant) width-subtyping is permitted ${ }^{1}$.

Synopsis. The present paper is organized as follows. In Section 2 we introduce the calculus $\lambda \mathcal{O} b j^{\oplus}$, its small-step operational semantics, and some intuitive examples to illustrate the idea of self-inflicted object extension. In Section 3 we define the type system for $\lambda \mathcal{O} b j^{\oplus}$ and discuss in detail the intended meaning of the most interesting rules. In Section 4 we show how our type system is compatible with a width-subtyping relation. Section 5 presents a collection of typing examples. In Section 6 we state our soundness result, namely that every closed and well-typed expression will not produce wrong results. Section 7 is devoted to workout an example, to illustrate the potential of the self-inflicted extension mechanism as a runtime feature, in connection with object reclassification. In Section 8 we discuss related work. The complete set of type assignment rules appears in the Appendix, together with full proofs.

[^0]The present work extends and completes [DGHL98] in the following way: we have slightly changed the reduction semantics, substantially refined the type system, fully documented the proofs, and, in the last two novel sections, we have connected our approach with the related developments in the area.

## 2 The lambda calculus of objects

In this section, we present the Lambda Calculus of Objects $\lambda \mathcal{O} b j^{\oplus}$. The terms are defined by the following abstract grammar:

$$
\begin{array}{rlr}
e::= & c|x| \lambda x . e\left|e_{1} e_{2}\right| & \text { ( } \lambda \text {-terms) } \\
& \rangle|\left\langle e_{1} \leftrightarrow m=e_{2}\right\rangle|e \Leftarrow m| & \text { (object-terms) } \\
& \operatorname{Sel}\left(e_{1}, m, e_{2}\right) & \text { (auxiliary-terms) }
\end{array}
$$

where $c, x, m$ are meta-variables ranging over sets of constants, variables, and names of methods, respectively. As usual, terms that differ only in the names of bound variables are identified. Terms are untyped $\lambda$-terms enriched with objects: the intended meaning of the object-terms is the following: $\left\rangle\right.$ stands for the empty object; $\left\langle e_{1} \oplus m=e_{2}\right\rangle$ stands for extending/overriding the object $e_{1}$ with a method $m$ whose body is $e_{2}$; $e \Leftarrow m$ stands for the result of sending the message $m$ to the object $e$.

The auxiliary operation $\operatorname{Sel}\left(e_{1}, m, e_{2}\right)$ searches the body of the $m$ method within the object $e_{1}$. In the recursive search of $m, \operatorname{Sel}\left(e_{1}, m, e_{2}\right)$ removes methods from $e_{1}$; for this reason we need to introduce the expression $e_{2}$, which denotes a function that, applied to $e_{1}$, reconstructs the original object with the complete list of its methods. This function is peculiar to the operational semantics and, in practice, could be made not available to the programmer.

To lighten up the notation, we write $\left\langle m_{1}=e_{1}, \ldots, m_{k}=e_{k}\right\rangle$ as syntactic sugar for $\left\langle\ldots\left\langle\left\rangle \oplus m_{1}=e_{1}\right\rangle \ldots \oplus m_{k}=e_{k}\right\rangle\right.$, where $k \geq 1$. Also, we write $e$ in place of $\lambda$ x.e if $x \notin F V(e)$; this mainly concerns methods, whose first formal parameter is always their host object: e.g. $\lambda s .1$ and $\lambda s^{\prime} .(s \Leftarrow m)$ are usually written 1 and $s \Leftarrow m$, respectively.

### 2.1 Operational semantics

We define the semantics of $\lambda \mathcal{O} b j^{\oplus}$ terms by means of the reduction rules displayed in Figure 1 (small-step semantics $\rightarrow$ ); the evaluation relation $\rightarrow$ is then taken to be the symmetric, reflexive, transitive and contextual closure of $\rightarrow$.

In addition to the standard $\beta$-rule for $\lambda$-calculus, the main operation on objects is method invocation, whose reduction is defined by the (Selection) rule. Sending a message $m$ to an object $e$ which contains a method $m$ reduces to $\operatorname{Sel}(e, m, \lambda s . s)$, where the arguments of Sel have the following intuitive meanings:
$1^{s t}$-arg. is a sub-object of the receiver (or recipient) of the message;
$2^{\text {nd }}$-arg. is the message we want to send to the receiver;
$3^{r d}$-arg. is a function that transforms the first argument in the original receiver.
By looking at the last two rules, one may note that the Sel function scans the receiver of the message until it finds the definition of the called method: when it finds such a method, it applies its body to the receiver of the message. Notice how the Sel function

| $($ Beta $)$ | $\left(\lambda x . e_{1}\right) e_{2}$ | $\rightarrow$ | $e_{1}\left[e_{2} / x\right]$ |
| :--- | :--- | :--- | :--- |
| (Selection $)$ | $e \Leftarrow m$ | $\rightarrow$ | $\operatorname{Sel}(e, m, \lambda s . s)$ |
| $($ Success $)$ | $\operatorname{Sel}\left(\left\langle e_{1} \hookleftarrow m=e_{2}\right\rangle, m, e_{3}\right)$ | $\rightarrow$ | $e_{2}\left(e_{3}\left\langle e_{1} \leftrightarrow m=e_{2}\right\rangle\right)$ |
| $($ Next $)$ | $\operatorname{Sel}\left(\left\langle e_{1} \oplus n=e_{2}\right\rangle, m, e_{3}\right)$ | $\rightarrow$ | $\operatorname{Sel}\left(e_{1}, m, \lambda s . e_{3}\left\langle s \leftrightarrow n=e_{2}\right\rangle\right)$ |

Figure 1 - Reduction Semantics (Small-Step)
carries over, in its search, all the informations necessary to reconstruct the original receiver of the message. The following reduction illustrates the evaluation mechanism:

$$
\begin{array}{ll}
\langle i d=\lambda s . s, \text { one }=1\rangle \Leftarrow i d & \rightarrow \\
\text { Sel }\left(\left\langle\langle d=\lambda s . s, \text { one }=1\rangle, \text { id, } \lambda s^{\prime} . s^{\prime}\right)\right. & \rightarrow \\
\operatorname{Sel}\left(\langle i d=\lambda s . s\rangle, \text { id, } \lambda s^{\prime \prime} .\left(\lambda s^{\prime} . s^{\prime}\right)\left\langle s^{\prime \prime} \leftrightarrow \text { one }=1\right\rangle\right) & \rightarrow \\
\operatorname{Sel}\left(\langle i d=\lambda s . s\rangle, \text { id, } \lambda s^{\prime \prime} \cdot\left\langle s^{\prime \prime} \oplus \text { one }=1\right\rangle\right) & \rightarrow \\
(\lambda s . s)\left(\left(\lambda s^{\prime \prime} .\left\langle s^{\prime \prime} \oplus \text { one }=1\right\rangle\right)\langle i d=\lambda s . s\rangle\right) & \rightarrow\langle i d=\lambda s . s, \text { one }=1\rangle
\end{array}
$$

That is, in order to call the first method $i d$ of an object-term with two methods, $\langle i d=\lambda$ s.s, one $=1\rangle$, one needs to consider the subterm containing just the first method $\langle i d=\lambda s . s\rangle$ and construct a function, $\lambda s^{\prime \prime} .\left\langle s^{\prime \prime} \leftrightarrow o n e=1\right\rangle$, transforming the subterm in the original term.

Proposition 2.1 The $\rightarrow$ reduction is Church-Rosser.
A quite simple technique to prove the Church-Rosser property for the $\lambda$-calculus has been proposed by Takahashi [Tak95]. The technique is based on parallel reduction and on Takahashi translation. It works as follows: first one defines a parallel reduction on $\lambda$-terms, where several redexes can be reduced in parallel; then one shows that for any term $e$ there is a term $e^{*}$, i.e. Takahashi's translation, obtained from $M$ by reducing a maximum set of redexes in parallel. It follows almost immediately that the parallel reduction satisfies the triangular property, hence the diamond property, and therefore the calculus in confluent. With respect to the $\lambda$-calculus, $\lambda \mathcal{O} b j^{\oplus}$ contains, besides the $\lambda$-rule, reduction rules for object terms; however, the latter do not interfere with the former, hence Takahashi's technique can be applied to the $\lambda \mathcal{O} b j^{\oplus}$ calculus.

A deterministic, call by name, evaluation strategy over terms $\xrightarrow{\text { det }}$ may be defined on $\lambda \mathcal{O} b j^{\oplus}$ by restricting the set of contexts used in the contextual closure of the reduction relation. In detail, we restrict the contextual closure to the set of contexts generated by the following grammar:

$$
C[]=[]|C[] e| C[] \Leftarrow m \mid \operatorname{Sel}(C[], m, e)
$$

The set of values, i.e. the terms that are well-formed (and typable according to the type system we introduce in Section 3) and where no reduction is possible, is defined by the following grammar:

$$
\begin{aligned}
o b j & ::=\langle \rangle \mid\left\langle e_{1} \oplus m=e_{2}\right\rangle \\
v & ::=c|\lambda x . e| o b j
\end{aligned}
$$

### 2.2 Examples

In the next examples we show three objects, performing, respectively:

- a self-inflicted extension;
- two (nested) self-inflicted extensions;
- a self-inflicted extension "on the fly".

Example 2.1 Consider the object selfext , defined as follows:

$$
\text { self }_{e x t} \triangleq\left\langle a d d_{n}=\lambda s .\langle s \leftrightarrow n=1\rangle\right\rangle .
$$

If we send the message $a d d_{n}$ to selfext , then we have the following computation:

$$
\begin{aligned}
& \text { selfext }^{\Leftarrow a d d_{n} \quad \rightarrow \quad \operatorname{Sel}\left(\text { self }_{f_{e x t}}, a d d_{n}, \lambda s^{\prime} . s^{\prime}\right), ~(x)} \\
& \rightarrow \quad(\lambda s .\langle s \leftarrow \oplus=1\rangle) \text { selfext } \\
& \rightarrow\left\langle\text { self }_{\text {ext }} \leftrightarrow \oplus n=1\right\rangle
\end{aligned}
$$

i.e. the method $n$ has been added to $s^{\text {self }} f_{\text {ext }}$. If we send the message $a d d_{n}$ twice to
 body; hence, we get an object which is "operationally equivalent" to the previous one.
Example 2.2 Consider the object inner $_{\text {ext }}$, defined as follows:

$$
\text { inner }_{e x t} \triangleq\left\langle a d d_{m n}=\lambda s .\left\langle s \leftrightarrow m=\lambda s^{\prime} .\left\langle s^{\prime} \leftrightarrow n=1\right\rangle\right\rangle\right\rangle
$$

If we send the message $a d d_{m n}$ to inner $_{e x t}$, then we obtain:

$$
\text { inner }_{\text {ext }} \Leftarrow a d d_{m n} \rightarrow\left\langle\text { inner }_{\text {ext }} \leftarrow \oplus m=\lambda s .\langle s \leftarrow n=1\rangle\right\rangle
$$

i.e. the method $m$ has been added to inner $_{\text {ext }}$. On the other hand, if we send first the message $a d d_{m n}$ and then $m$ to inner $_{\text {ext }}$, both the methods $m$ and $n$ are added:

$$
\begin{aligned}
\\
\left(\text { inner }_{\text {ext }} \Leftarrow a d d_{m n}\right) \Leftarrow m \quad \rightarrow \quad \begin{array}{ll}
\left\langle a d d_{m n}\right. & =\lambda s .\left\langle s \leftarrow \oplus=\lambda s^{\prime} .\left\langle s^{\prime} \leftrightarrow \oplus n=1\right\rangle\right\rangle, \\
m & =\lambda s .\langle s \leftrightarrow n=1\rangle, \\
n & =1\rangle
\end{array}, l
\end{aligned}
$$

Example 2.3 Consider the object $f l y_{\text {ext }}$, defined as follows:

$$
f l y_{e x t} \triangleq\left\langle f=\lambda s . \lambda s^{\prime} . s^{\prime} \Leftarrow n, \text { get }_{f}=\lambda s .(s \Leftarrow f)\langle s \leftarrow n=1\rangle\right\rangle
$$

If we send the message get $_{f}$ to $f l y_{\text {ext }}$, then we get the following computation:

$$
\begin{aligned}
f l y_{e x t} \Leftarrow g e t_{f} & \rightarrow \operatorname{Sel}\left(f l y_{\text {ext }}, g e t_{f}, \lambda s^{\prime \prime} . s^{\prime \prime}\right) \\
& \rightarrow(\lambda s .(s \Leftarrow f)\langle s \hookleftarrow n=1\rangle) f l y_{\text {ext }} \\
& \rightarrow\left(f l y_{\text {ext }} \Leftarrow f\right)\left\langle f l y_{\text {ext }} \oplus n=1\right\rangle \\
& \rightarrow \operatorname{Sel}\left(f l y_{\text {ext }}, f, \lambda s^{\prime \prime} . s^{\prime \prime}\right)\left\langle\text { fly }_{\text {ext }} \oplus n=1\right\rangle \\
& \rightarrow\left(\lambda s . \lambda s^{\prime} . s^{\prime} \Leftarrow n\right) \text { fly }_{\text {ext }}\left\langle f l y_{\text {ext }} \oplus n=1\right\rangle \\
& \rightarrow\left\langle f l y_{\text {ext }} \oplus n=1\right\rangle \Leftarrow n \\
& \rightarrow 1
\end{aligned}
$$

i.e. the following steps are performed:

1. the method get $_{f}$ calls the method $f$ with actual parameter the host object itself augmented with the $n$ method;
2. the $f$ method takes as input the host object augmented with the $n$ method, and sends to this object the message $n$, which simply returns the constant 1 .

## 3 Type system

In this section, we introduce the syntax of types and we discuss the most interesting type rules. For the sake of simplicity, we prefer to first present the type system without the rules related with object subsumption (which will be discussed in Section 4). The complete set of rules can be found in Appendices A and B.

### 3.1 Types

The type expressions are described by the following grammar:

$$
\begin{array}{rlr}
\sigma & ::=\iota|\sigma \rightarrow \sigma| \tau & \text { (generic-types) } \\
\tau & ::=t \mid \text { prot.R| } \uparrow \oplus m & \text { (object-types) } \\
R & ::=\langle \rangle \mid\langle R, m: \sigma\rangle & \text { (rows) } \\
\kappa & ::=* & \text { (kind of types) }
\end{array}
$$

In the rest of the article we will use $\sigma$ as meta-variable ranging over generic-types, $\iota$ over constant types, $\tau$ over object-types. Moreover, $t$ is a type variable, $R$ a metavariable ranging over rows, i.e. unordered sets of pairs (method label, method type), $m$ a method label, and $\kappa$ a metavariable ranging over the unique kind of types $*$.

To ease the notation, we write $\left\langle\ldots\left\langle\left\rangle, m_{1}: \sigma_{1}\right\rangle \ldots, m_{k}: \sigma_{k}\right\rangle\right.$ as $\left\langle m_{1}: \sigma_{1}, \ldots, m_{k}: \sigma_{k}\right\rangle$ or $\left\langle\bar{m}_{k}: \bar{\sigma}_{k}\right\rangle$ or else simply $\langle\bar{m}: \bar{\sigma}\rangle$ in the case the subscripts can be omitted. Similarly, we write either $\tau \oplus \bar{m}_{k}$ or $\tau \oplus \bar{m}$ for $\tau \oplus m_{1} \ldots \oplus m_{k}$, and $\tau \oplus \bar{m}, n$ for $\tau \oplus m_{1} \ldots \oplus m_{k} \oplus n$. If $R \equiv\langle\bar{m}: \bar{\sigma}\rangle$, then we denote $\bar{m}$ by $\bar{R}$, and we write $R_{1} \subseteq R_{2}$ if $R_{1} \equiv\left\langle\bar{m}: \bar{\sigma}_{1}\right\rangle$ and $R_{2} \equiv\left\langle\bar{m}: \bar{\sigma}_{1}, \bar{n}: \bar{\sigma}_{2}\right\rangle$.

As in [FHM94], we may consider object-types as a form of recursively-defined types. Object-types in the form prot. $R \oplus \bar{m}$ are named pro-types, where pro is a binder for the type-variable $t$ representing "self" (we use $\alpha$-conversion of type-variables bound by pro). The intended meaning of a pro-type prot. $\langle\bar{m}: \bar{\sigma}\rangle \oplus \bar{n}$ is the following:

- the methods in $\bar{m}$ are the ones which are present in the pro-type;
- the methods in $\bar{n}$, being in fact a subset of those in $\bar{m}$, are the methods that are available and can be invoked (it follows that the pro-type prot. $\langle\bar{m}: \bar{\sigma}\rangle \oplus \bar{m}$ corresponds exactly to the object-type classt. $\langle\bar{m}: \bar{\sigma}\rangle$ in [FHM94]);
- the methods in $\bar{m}$ that do not appear in $\bar{n}$ are methods that cannot be invoked: they are just reserved.

In the end, we can say that the operator " $\oplus$ " is used to make active and usable those methods that were previously just reserved in a pro-type; essentially, $\oplus$ is the "type counterpart" of the operator on terms $\oplus$. In the following, it will turn out that we can extend an object $e$ with a new method $m$ having type $\sigma$ only if it is possible to assign to $e$ an object-type of the form $\operatorname{prot} .\langle R, m: \sigma\rangle \oplus \bar{n}, m$; this reservation mechanism is crucial to guarantee the soundness of the type system.

### 3.2 Contexts and judgments

The contexts have the following form:

$$
\Gamma::=\varepsilon|\Gamma, x: \sigma| \Gamma, t \nVdash \tau
$$

Our type assignment system uses judgments of the following shapes:

$$
\Gamma \vdash o k \quad \Gamma \vdash \sigma: * \quad \Gamma \vdash e: \sigma \quad \Gamma \vdash \tau_{1} \nVdash \tau_{2}
$$

The intended meaning of the first three judgments is standard: well-formed contexts and types, and assignment of type $\sigma$ to term $e$. The intended meaning of $\Gamma \vdash \tau_{1} \not \sharp \tau_{2}$ is that $\tau_{1}$ is the type of a possible extension of an object having type $\tau_{2}$. As in [Bru94], and in [BL95, BBL96, BBDL97, BB99], this judgment formalizes the notion of method-specialization (or protocol-extension), i.e. the capability to "inherit" the type of the methods of the prototype.

### 3.3 Well formed context and types

The type rules for well-formed contexts are quite standard. We just remark that in the (Cont-t) rule:

$$
\frac{\Gamma \vdash p r o t . R \oplus \bar{m}: * \quad t \notin \operatorname{Dom}(\Gamma)}{\Gamma, t \nVdash \text { prot. } R \oplus \bar{m} \vdash o k}
$$

we require that the object-types used to bind variables are not variable types themselves: this condition does not have any serious restriction, and has been set in the type system in order to make simpler the proofs of its properties.

The (Type-Pro) rule:

$$
\frac{\Gamma, t \not \sharp \text { prot. } R \vdash \sigma: * \quad m \notin \bar{R}}{\Gamma \vdash \operatorname{prot} .\langle R, m: \sigma\rangle: *}
$$

asserts that the object-type prot. $\langle R, m: \sigma\rangle$ is well-formed if the object-type prot. $R$ is well-formed and the type $\sigma$ is well-formed under the hypothesis that $t$ is an object-type containing the methods in $\bar{R}$. Since $\sigma$ may contain a subexpression of the form $t \oplus n$, with $n \in \bar{R}$, we need to introduce in the context the hypothesis $t \not \sharp p r o t . R$ to prove that $t \oplus n$ is a well-formed type.

The (Type-Extend) rule:

$$
\frac{\Gamma \vdash \tau \nVdash \text { prot. } R \quad \bar{m} \subseteq \bar{R}}{\Gamma \vdash \tau \oplus \bar{m}: *}
$$

asserts that in order to activate the methods $\bar{m}$ in the object-type $\tau$, the methods $\bar{m}$ need to be present (reserved) in $\tau$.

### 3.4 Matching rules

The (Match-Pro) rule:

$$
\frac{\Gamma \vdash \text { prot. } R_{1} \oplus \bar{m}: * \quad \Gamma \vdash \text { prot. } R_{2} \oplus \bar{n}: * \quad R_{2} \subseteq R_{1} \quad \bar{n} \subseteq \bar{m}}{\Gamma \vdash \text { prot. } R_{1} \oplus \bar{m} \nVdash \text { prot. } R_{2} \oplus \bar{n}}
$$

asserts that an object-type with more reserved and more available methods specializes an object-type with less reserved and less available methods.

The (Match-Var) rule:

$$
\frac{\Gamma_{1}, t \nVdash \tau_{1}, \Gamma_{2} \vdash \tau_{1} \oplus \bar{m} \nVdash \tau_{2}}{\Gamma_{1}, t \nVdash \tau_{1}, \Gamma_{2} \vdash t \oplus \bar{m} \sharp \tau_{2}}
$$

makes available the matching judgments present in the context. It asserts that, if a context contains the hypothesis that a type variable $t$ specializes a type $\tau_{1}$, and $\tau_{1}$ itself, incremented with a set of methods $\bar{m}$, specializes a type $\tau_{2}$, then, by transitivity of the matching relation, $t$, incremented by the methods in $\bar{m}$, specializes $\tau_{2}$.

The (Match-t) rule:

$$
\frac{\Gamma \vdash t \oplus \bar{m}: * \quad \bar{n} \subseteq \bar{m}}{\Gamma \vdash t \oplus \bar{m} \nVdash t \oplus \bar{n}}
$$

concerns object-types built from the same type variable, simply asserting that a type with more available methods specializes a type with less available methods.

### 3.5 Terms rules

The type rules for $\lambda$-terms are self-explanatory and hence they need no further justification. Concerning those for object terms, the (Empty) rule assigns to an empty object an empty pro-type, while the (Pre-Extend) rule:

$$
\frac{\Gamma \vdash e: \operatorname{prot} . R_{1} \oplus \bar{m} \quad \Gamma \vdash \operatorname{prot} .\left\langle R_{1}, R_{2}\right\rangle \oplus \bar{m}: *}{\Gamma \vdash e: \operatorname{prot} .\left\langle R_{1}, R_{2}\right\rangle \oplus \bar{m}}
$$

asserts that an object $e$ having type prot. $R_{1} \oplus \bar{m}$ can be considered also an object having type prot. $\left\langle R_{1}, R_{2}\right\rangle \oplus \bar{m}$, i.e. with more reserved methods. This rule has to be used in conjunction with the (Extend) one; it ensures that we can dynamically add fresh methods. Notice that (Pre-Extend) cannot be applied when $e$ is a variable $s$ representing self; in fact, as explained in the Remark 3.1 below, the type of $s$ can only be a type variable. This fact is crucial for the soundness of the type system.

The (Extend) rule:

$$
\begin{gathered}
\Gamma \vdash e_{1}: \tau \quad \Gamma \vdash \tau \nVdash \text { prot. }\langle R, n: \sigma\rangle \oplus \bar{m} \\
\frac{\Gamma, t \nVdash \text { prot. }\langle R, n: \sigma\rangle \oplus \bar{m}, n \vdash e_{2}: t \rightarrow \sigma}{\Gamma \vdash\left\langle e_{1} \oplus n=e_{2}\right\rangle: \tau \oplus n}
\end{gathered}
$$

can be applied in the following cases:

1. when the object $e_{1}$ has type $\operatorname{prot} .\langle R, n: \sigma\rangle \oplus \bar{m}$ (or, by a previous application of the (Pre-Extend) rule, prot. $R \oplus \bar{m}$ ). In this case the object $e_{1}$ is extended with the (fresh) method $n$;
2. when $\tau$ is a type variable $t$. In this case $e_{1}$ can be the variable s, and a self-inflicted extension takes place.

The bound for $t$ is the same as the final type for the object $\left\langle e_{1} \oplus n=e_{2}\right\rangle$; this allows a recursive call of the method $n$ inside the expression $e_{2}$, defining the method $n$ itself.

The (Override) rule:

$$
\begin{gathered}
\Gamma \vdash e_{1}: \tau \quad \Gamma \vdash \tau \nVdash \text { prot. }\langle R, n: \sigma\rangle \oplus \bar{m}, n \\
\Gamma, t \nVdash \text { prot. }\langle R, n: \sigma\rangle \oplus \bar{m}, n \vdash e_{2}: t \rightarrow \sigma \\
\Gamma \vdash\left\langle e_{1} \oplus n=e_{2}\right\rangle: \tau
\end{gathered}
$$

is quite similar to the (Extend) rule, but it is applied when the method $n$ is already available in the object $e_{1}$, hence the body of $n$ is overridden with a new one.

Remark 3.1 By inspecting the (Extend) and (Override) rules, one can see why the type of the object itself is always a type variable. In fact, the body $e_{2}$ of the new added method $n$ needs to have type $t \rightarrow \sigma$. Therefore, if $e_{2}$ reduces to a value, this value has to be a $\lambda$-abstraction in the form $\lambda s . e_{2}^{\prime}$. It follows that, in assigning a type to $e_{2}^{\prime}$, we must use a context containing the hypothesis $s: t$. Since no subsumption rule is available, the only type we can deduce for $s$ is $t$.

The (Send) rule:

$$
\frac{\Gamma \vdash e: \tau}{} \quad \Gamma \vdash \tau \nVdash \text { prot. }\langle R, n: \sigma\rangle \oplus \bar{m}, n,
$$

is the standard rule that one can expect from a type system based on matching. We require that the method we are invoking is available in the recipient of the message.

In the (Select) rule:

$$
\begin{gathered}
\Gamma \vdash e_{1}: \tau \quad \Gamma \vdash \tau \nVdash \text { prot. }\langle R, n: \sigma\rangle \oplus \bar{m}, n \\
\Gamma, t \nVdash \text { prot. }\langle R, n: \sigma\rangle \oplus \bar{m}, n \vdash e_{2}: t \rightarrow t \oplus \bar{n} \\
\Gamma \vdash \operatorname{Sel}\left(e_{1}, n, e_{2}\right): \sigma[\tau \oplus \bar{n} / t]
\end{gathered}
$$

the first two conditions ensure that the $n$ method is available in $e_{1}$, while the last one that $e_{2}$ is a function that transforms an object into a more refined one.

## 4 Dealing with object subsumption

While the type assignment system $\lambda \mathcal{O} b j^{\oplus}$, presented in Section 3, allows self-inflicted extension, it does not allow object subsumption. This is not surprising: in fact, we could (by subsumption) first hide a method in an object, and then add it again with a type incompatible with the previous one. The papers [AC96, FM94, FHM94, BL95] propose different type systems for prototype-based languages, where subsumption is permitted only in absence of object extension (and a fortiori self-inflicted extension). In this section, we devise a conservative extension of $\lambda \mathcal{O} b j^{\oplus}$, that we name $\lambda \mathcal{O} b j_{S}^{\oplus}$ (Appendix B collects its extra rules), to accommodate width-subtyping.

In the perspective of adding a subsumption rule to the typing system, we introduce another kind of object-types, i.e. objt. $R \oplus \bar{m}$, named obj-types. The main difference between the pro-types and the obj-types consists in the fact that the (Pre-Extend) rule cannot be applied when an object has type objt.R $\oplus \bar{m}$; it follows that the type objt. $R \oplus \bar{m}$ permits extensions of an object only by enriching the list $\bar{m}$, i.e. by making active its reserved methods. This approach to subsumption is inspired by the one in [FM95, Liq97]. Formally, we need to extend the syntax of types by means of obj-types and the kind of rigid, i.e. non-extensible, types:

$$
\begin{array}{rlr}
\tau::=\ldots \mid \text { objt.R } & \text { (object-types) } \\
\kappa::=\ldots \mid *_{r g d} & \text { (kind of types) }
\end{array}
$$

The subset of rigid types contains the obj-types and is closed under the arrow constructor. In order to axiomatize this, we introduce the judgment $\Gamma \vdash \tau: *_{r g d}$, whose rules are reported in Appendix B. Intuitively, we can use the matching relation as a subtyping relation only when the type in the conclusion is rigid:

$$
\frac{\Gamma \vdash e: \tau_{1} \quad \Gamma \vdash \tau_{1} \sharp \tau_{2} \quad \Gamma \vdash \tau_{2}: *_{\text {rgd }}}{\Gamma \vdash e: \tau_{2}} \text { (Subsume) }
$$

Let be $\tau \triangleq \operatorname{prot} .\left\langle a d d_{n}: t \oplus n, n: i n t\right\rangle$ and $\Gamma \triangleq t \nVdash \tau \oplus a d d_{n}$, s:t. Then:

$$
\frac{\frac{\vdots}{\vdash\rangle: \tau} \quad \frac{\vdots}{\vdash \tau \sharp \tau} \quad \Delta}{\vdash\left\langle a d d_{n}=\lambda s .\langle s \hookleftarrow n=1\rangle\right\rangle: \tau \oplus a d d_{n}} \text { (Extend) }
$$

where the first two premises are derived straightforwardly and $\Delta$ as follows:

$$
\frac{\Gamma \vdash s: t \quad \Gamma \vdash t \nVdash \text { prot. }\langle n: i n t\rangle \quad \Gamma, t^{\prime} \nVdash p r o t^{\prime} .\langle n: i n t\rangle \oplus n \vdash 1: t^{\prime} \rightarrow \text { int }}{\Gamma \vdash\langle s \leftrightarrow \oplus=1\rangle: t \oplus n} \text { (Extend) }
$$

Figure 2 - A derivation for selfext

This is in fact is the rule performing object subsumption: it allows to use objects with an extended signature in any context expecting objects with a shorter one.

It is important to point out that, so doing, we do not need to introduce another partial order on types, i.e. an ordinary subtyping relation, to deal with subsumption. By introducing the sub-kind of rigid types, we make the matching relation compatible with subsumption, and hence we can make it play the role of the width-subtyping relation. This is in sharp contrast with the uses of matching proposed in the literature ([Bru94, BPF97, BB99]). Hence, in our type assignment system, the matching is a relation on types compatible with a limited subsumption rule.

Most of the rules for obj-types are a rephrasing of the rules presented so far, replacing the binder pro with obj. We remark that the (Type $-O b j-R d g$ ) rule

$$
\frac{\Gamma \vdash o b j t .\left\langle\bar{m}_{k}: \bar{\sigma}_{k}\right\rangle \oplus \bar{n}: * \quad \forall i \leq k . \Gamma \vdash \sigma_{i}: *_{r g d} \wedge t \text { covariant in } \sigma_{i}}{\Gamma \vdash \text { objt. }\left\langle\bar{m}_{k}: \bar{\sigma}_{k}\right\rangle \oplus \bar{n}: *_{r g d}}
$$

asserts that subsumption is unsound for methods having $t$ in contravariant position with respect to the arrow type constructor. Therefore, the variable $t$ is forced to occur only covariantly in $\bar{\sigma}_{k}$. A natural (and sound) consequence is that we cannot forget binary methods via subtyping (see $\left[\mathrm{BCC}^{+} 96\right.$, Cas 95 , Cas 96$]$ ). The (Promote) rule

$$
\frac{\Gamma \vdash \text { prot. } R_{1} \oplus \bar{m}: * \quad \Gamma \vdash \text { objt. } R_{2} \oplus \bar{n}: * \quad R_{2} \subseteq R_{1} \quad \bar{n} \subseteq \bar{m}}{\Gamma \vdash \text { prot. } R_{1} \oplus \bar{m} \nVdash o b j t . R_{2} \oplus \bar{n}}
$$

promotes a fully-specializable pro-type into a limitedly specializable obj-type with less reserved and less available methods.

## 5 Examples

In this section, we give the types of the examples presented in Section 2.2, together with some other motivating examples. The objects self ext, inner $_{\text {ext }}$, and $f l y_{\text {ext }}$, of Examples 2.1, 2.2, and 2.3, respectively, can be given the following types:

$$
\begin{aligned}
\text { self }_{\text {ext }} & : \operatorname{prot.}\left\langle a d d_{n}: t \oplus n, n: i n t\right\rangle \oplus a d d_{n} \\
\text { inner }_{\text {ext }} & : \operatorname{prot.}\left\langle a d d_{m n}: t \oplus m, m: t \oplus n, n: i n t\right\rangle \oplus a d d_{m n} \\
\text { fly }_{\text {ext }} & : \operatorname{prot} .\left\langle f: t \oplus n, \text { get } f_{f}: t \oplus n \rightarrow i n t, n: i n t\right\rangle \oplus f, \text { get }_{f}
\end{aligned}
$$

A possible derivation for selfext is presented in Figure 2.
Example 5.1 We show how class declaration can be simulated in $\lambda \mathcal{O} b j^{\oplus}$ and how using the self-inflicted extension we can factorize in a single declaration the definition of a hierarchy of classes. Let the method add col be defined as in Example 1.1, and let us consider the simple class definition:

$$
P_{\text {class }} \triangleq\left\langle n e w=\lambda s .\left\langle n=1, a d d_{c o l}=\lambda s^{\prime} . \lambda x .\left\langle s^{\prime} \leftrightarrow c o l=x\right\rangle\right\rangle\right\rangle
$$

Then, the object $P_{\text {class }}$ can be used to create instances of both points and colored points, by using the expressions:

$$
P_{\text {class }} \Leftarrow \text { new } \quad \text { and } \quad\left(P_{\text {class }} \Leftarrow \text { new }\right) \Leftarrow a d d_{\text {col }}(\text { white })
$$

Example 5.2 (Subsumption 1) We show how subsumption can interact with object extension. Let be:

$$
\begin{aligned}
P & \triangleq \text { objt. }\langle n: i n t, \text { col:color }\rangle\rangle \oplus n \\
C P & \triangleq \text { objt. }\langle n: i n t, \text { col:color }\rangle \oplus n, \text { col } \\
g & \triangleq \lambda s .\langle s \oplus \mathrm{col}=\text { white }\rangle
\end{aligned}
$$

and let $p$ and $c p$ be of type $P$ and $C P$, respectively. Then, we can derive:

$$
\begin{aligned}
& \vdash C P \nVdash P \quad \vdash g: P \rightarrow C P \quad \vdash g(c p): C P \\
& \vdash(\lambda f \text {.equal }(f(p) \Leftarrow \operatorname{col}, f(c p) \Leftarrow c o l)) g: \text { bool }
\end{aligned}
$$

where the equality function equal has type $t \rightarrow t \rightarrow$ bool. Notice that the terms:

$$
g(c p) \quad(\lambda f . e q u a l(f(p) \Leftarrow \operatorname{col}, f(c p) \Leftarrow \operatorname{col}))
$$

would not be typable without the subsumption rule.
Example 5.3 (Subsumption 2) We show how subsumption can interact with object self-inflicted extension. Let be:

$$
\begin{aligned}
Q & \triangleq \text { objt. }\langle n: i n t\rangle \oplus n \\
q & \triangleq\left\langle\text { copy }_{n}=\lambda s . \lambda s^{\prime} .\left\langle s \hookleftarrow n=s^{\prime} \Leftarrow n\right\rangle\right\rangle
\end{aligned}
$$

By assuming p and cp as in Example 5.2, we can derive:

$$
\begin{aligned}
\vdash q & : \operatorname{prot} .\left\langle\operatorname{copy}_{n}: Q \rightarrow t \oplus n, n: i n t\right\rangle \oplus \operatorname{copy}_{n} \\
\vdash q \Leftarrow \operatorname{copy}_{n}(c p) & : \operatorname{prot} .\left\langle n: i n t, \operatorname{copy}_{n}: Q \rightarrow t\right\rangle \oplus n, \operatorname{copy}_{n} \\
\vdash q \Leftarrow \operatorname{copy}_{n}(c p) \Leftarrow \operatorname{copy}_{n}(p) & : \operatorname{prot} .\left\langle n: i n t, c^{c o p y_{n}}: Q \rightarrow t\right\rangle \oplus n, \text { copy }_{n}
\end{aligned}
$$

Notice in particular that the object $q \Leftarrow \operatorname{copy}_{n}(c p) \Leftarrow \operatorname{copy}_{n}(p)$ would not be typable without the subsumption rule.

Example 5.4 (Downcasting) The self-inflicted extension permits to perform explicit downcasting simply by method calling. In fact, let $p_{1}$ and $c p_{1}$ be objects with eq methods (checking the values of $n$ and the pairs ( $n$, col), respectively), and add $d_{\text {col }}$ the self-extension method presented in Example 5.1, typable as follows:

$$
\vdash p_{1}: \text { prot. } R \quad \text { and } \quad \vdash c p_{1}: \text { prot. } R \oplus \text { col }
$$

where $R \triangleq\langle n: i n t$, eq: $t \rightarrow$ bool, add col:colors $\rightarrow t \oplus$ col, col:color $\rangle\rangle \oplus n, e q, a d d_{c o l}$. Then, the following judgments are derivable:

$$
\begin{aligned}
& \vdash c p_{1} \Leftarrow e q: \text { prot. } R \oplus \text { col } \rightarrow \text { bool } \\
& \vdash p_{1} \Leftarrow a d d_{\text {col }}(\text { white }): \text { prot. } R \oplus \text { col } \\
& \vdash c p_{1} \Leftarrow e q\left(p_{1} \Leftarrow a d d_{\text {col }}(\text { white })\right): \\
& \text { bool }
\end{aligned}
$$

## 6 Soundness of the Type System

In this section, we prove the crucial property of our type system, i.e. the Subject Reduction theorem. It needs a preliminary series of technical lemmas presenting basic and technical properties, which are proved by inductive arguments. As a corollary, we shall derive the fundamental result of the paper, i.e. the Type Soundness of our typing discipline.

We first address the plain type assignment system without subsumption $\lambda \mathcal{O} b j^{\oplus}$, then in Section 6.1 we extend the Subject Reduction to the whole type system $\lambda \mathcal{O} b j_{S}^{\oplus}$. The proofs are fully documented in Appendices C and D.

In the presentation of the formal results, we need $\alpha, \beta$ as metavariables for generictypes and $\rho, v$ for object-types. Moreover, $\mathcal{A}$ is a metavariable ranging on statements in the forms $o k, \alpha: *, v \nVdash \rho, e: \beta$, and $\mathcal{C}$ on statements in the forms $x: \sigma, t \nVdash \tau$.

Lemma 6.1 (Sub-derivation)
(i) If $\Delta$ is a derivation of $\Gamma_{1}, \Gamma_{2} \vdash \mathcal{A}$, then there exists a sub-derivation $\Delta^{\prime} \subseteq \Delta$ of $\Gamma_{1} \vdash o k$.
(ii) If $\Delta$ is a derivation of $\Gamma_{1}, x: \sigma, \Gamma_{2} \vdash \mathcal{A}$, then there exists a sub-derivation $\Delta^{\prime} \subseteq \Delta$ of $\Gamma_{1} \vdash \sigma: *$.
(iii) If $\Delta$ is a derivation of $\Gamma_{1}, t \not \sharp \tau, \Gamma_{2} \vdash \mathcal{A}$, then there exists a sub-derivation $\Delta^{\prime} \subseteq \Delta$ of $\Gamma_{1} \vdash \tau: *$.

Lemma 6.2 (Weakening)
(i) If $\Gamma_{1}, \Gamma_{2} \vdash \mathcal{A}$ and $\Gamma_{1}, \mathcal{C}, \Gamma_{2} \vdash$ ok, then $\Gamma_{1}, \mathcal{C}, \Gamma_{2} \vdash \mathcal{A}$.
(ii) If $\Gamma_{1} \vdash \mathcal{A}$ and $\Gamma_{1}, \Gamma_{2} \vdash o k$, then $\Gamma_{1}, \Gamma_{2} \vdash \mathcal{A}$.

Lemma 6.3 (Well-formed object-types)
(i) $\Gamma \vdash$ prot. $R \oplus \bar{m}: *$ if and only if $\Gamma \vdash \operatorname{prot} . R: *$ and $\bar{m} \subseteq \bar{R}$.
(ii) $\Gamma \vdash t \oplus \bar{m}: *$ if and only if $\Gamma$ contains $t \not \sharp$ prot. $R \oplus \bar{n}$, with $\bar{m} \subseteq \bar{R}$.

Proposition 6.4 (Matching is well-formed)
If $\Gamma \vdash \tau_{1} \sharp \tau_{2}$, then $\Gamma \vdash \tau_{1}: *$ and $\Gamma \vdash \tau_{2}: *$.
Lemma 6.5 (Matching)
(i) $\Gamma \vdash$ prot. $R_{1} \oplus \bar{m} \nVdash \tau_{2}$ if and only if $\Gamma \vdash$ prot. $R_{1} \oplus \bar{m}: *$ and $\Gamma \vdash \tau_{2}: *$ and $\tau_{2} \equiv$ prot. $R_{2} \oplus \bar{n}$, with $R_{2} \subseteq R_{1}$ and $\bar{n} \subseteq \bar{m}$.
(ii) $\Gamma \vdash \tau_{1} \nVdash t \oplus \bar{n}$ if and only if $\Gamma \vdash \tau_{1}: *$ and $\tau_{1} \equiv t \oplus \bar{m}$, with $\bar{n} \subseteq \bar{m}$.
(iii) $\Gamma \vdash t \oplus \bar{m} \nVdash$ prot. $R_{2} \oplus \bar{n}$ if and only if $\Gamma$ contains $t \not \sharp$ prot. $R_{1} \oplus \bar{p}$, with $R_{2} \subseteq R_{1}$ and $\bar{n} \subseteq \bar{m} \cup \bar{p}$.
(iv) (Reflexivity) If $\Gamma \vdash \rho: *$ then $\Gamma \vdash \rho \nVdash \rho$.
(v) (Transitivity) If $\Gamma \vdash \tau_{1} \sharp \not \rho$ and $\Gamma \vdash \rho \nVdash \tau_{2}$, then $\Gamma \vdash \tau_{1} \sharp \tau_{2}$.
(vi) (Uniqueness) If $\Gamma \vdash \tau_{1} \nVdash$ prot. $\left\langle R_{1}, m: \sigma_{1}\right\rangle$ and $\Gamma \vdash \tau_{1} \nVdash$ prot. $\left\langle R_{2}, m: \sigma_{2}\right\rangle$, then $\sigma_{1} \equiv \sigma_{2}$.
(vii) If $\Gamma \vdash \tau_{1} \nVdash \tau_{2}$ and $\Gamma \vdash \tau_{2} \oplus m: *$, then $\Gamma \vdash \tau_{1} \oplus m \nVdash \tau_{2} \oplus m$.
(viii) If $\Gamma \vdash \tau_{1} \oplus m \not \sharp$ prot. $R \oplus \bar{n}$, then $\Gamma \vdash \tau_{1} \nVdash$ prot. $R \oplus \bar{n}-m$.
(ix) If $\Gamma \vdash \rho \oplus m: *$, then $\Gamma \vdash \rho \oplus m \nVdash \rho$.

Lemma 6.6 (Match Weakening)
(i) If $\Gamma_{1}, t \not \sharp \rho, \Gamma_{2} \vdash \mathcal{A}$ and $\Gamma_{1} \vdash \tau \not \sharp \rho$, with $\tau$ a pro-type, then $\Gamma_{1}, t \not \sharp \tau, \Gamma_{2} \vdash \mathcal{A}$.
(ii) If $\Gamma \vdash \operatorname{prot} .\langle R, n: \sigma\rangle \oplus \bar{m}: *$, then $\Gamma, t \nVdash$ prot. $\langle R, n: \sigma\rangle \oplus \bar{m} \vdash \sigma: *$.

## Proposition 6.7 (Substitution)

(i) If $\Gamma_{1}, x: \sigma, \Gamma_{2} \vdash \mathcal{A}$ and $\Gamma_{1} \vdash e: \sigma$, then $\Gamma_{1}, \Gamma_{2} \vdash \mathcal{A}[e / x]$.
(ii) If $\Gamma_{1}, t \nVdash \tau, \Gamma_{2}, \Gamma_{3} \vdash \mathcal{A}$ and $\Gamma_{1}, t \nVdash \tau, \Gamma_{2} \vdash \rho \nVdash \tau$, then $\Gamma_{1}, t \nVdash \tau, \Gamma_{2}, \Gamma_{3}[\rho / t] \vdash$ $\mathcal{A}[\rho / t]$.
(iii) If $\Gamma_{1}, t \nVdash \tau, \Gamma_{2} \vdash \mathcal{A}$ and $\Gamma_{1} \vdash \rho \nVdash \tau$, then $\Gamma_{1}, \Gamma_{2}[\rho / t] \vdash \mathcal{A}[\rho / t]$.

Proposition 6.8 (Types of expressions are well-formed)
If $\Gamma \vdash e: \beta$, then $\Gamma \vdash \beta: *$.
Finally, we can state the key Subject Reduction property for our type system.
Theorem 6.9 (Subject Reduction, $\lambda \mathcal{O b j}{ }^{\oplus}$ ) If $\Gamma \vdash e: \beta$ and $e \rightarrow e^{\prime}$, then $\Gamma \vdash e^{\prime}: \beta$.
We proceed by deriving the Type Soundness theorem: it guarantees, among other properties, that every closed and well-typed expression will not produce the message-not-found runtime error. This error arises whenever we search for a method $m$ into an expression that does not reduce to an object which has the method $m$ in its interface.

Definition 6.10 We define the set of wrong terms as follows:

$$
\text { wrong }::=\operatorname{Sel}(\langle \rangle, m, e)\left|\operatorname{Sel}\left((\lambda x . e), m, e^{\prime}\right)\right| \operatorname{Sel}(c, m, e)
$$

By a direct inspection of the typing rules for terms, one can immediately see that wrong cannot be typed. Hence, the Type Soundness follows as a corollary of the Subject Reduction theorem.

Corollary 6.11 (Type Soundness) If $\varepsilon \vdash e: \beta$, then $e \nrightarrow C[$ wrong $]$, where $C[]$ is a generic context in $\lambda \mathcal{O} b j^{\oplus}$, i.e. a term with an "hole" inside it.

### 6.1 Soundness of the Type System with Subsumption

The proof of the Type Soundness concerning the type assignment system with subsumption $\lambda \mathcal{O} b j_{S}^{\oplus}$ is quite similar to the corresponding proof for the plain type system. In particular, all the preliminary lemmas and their corresponding proofs remain almost the same; only the proof of the crucial Theorem 6.9 needs to be modified significantly. Therefore, we do not document the whole proofs of the preliminary lemmas, but we just remark the points where new arguments are needed.

In fact, Lemmas 6.1 (Sub-derivation), 6.2 (Weakening), 6.4 (Matching is wellformed), 6.7 (Substitution), 6.8 (Types of expressions are well-formed) are valid also for the type assignment with subsumption. Conversely, we need to rephrase Lemmas 6.3 (Well-formed object-types), 6.5 (Matching), 6.6 (Match Weakening), as follows.

In Lemma (Well-formed object-types) 6.3, the point (ii) needs to be rewritten as:
(ii) $\Gamma \vdash t \oplus \bar{m}: *$ if and only if $\Gamma$ contains either $t \not \sharp p r o t . R \oplus \bar{n}$ or $t \nVdash o b j t . R \oplus \bar{n}$, with $\bar{m} \subseteq \bar{R}$.

In Lemma (Matching) 6.5, the point (vi) needs to be rewritten as:
(vi) (Uniqueness) if $\Gamma \vdash \tau_{1} \not \sharp$ objt. $\left\langle R_{1}, m: \sigma_{1}\right\rangle$ and $\Gamma \vdash \tau_{1} \not \sharp$ objt. $\left\langle R_{2}, m: \sigma_{2}\right\rangle$, then $\sigma_{1} \equiv \sigma_{2}$.

Moreover, in the same lemma the following points need to be added:
(i') $\Gamma \vdash$ objt. $R_{1} \oplus \bar{m} \nVdash \tau_{2}$ if and only if $\Gamma \vdash \operatorname{prot} . R_{1} \oplus \bar{m}: *$ and $\Gamma \vdash \tau_{2}: *$ and $\tau_{2} \equiv$ objt. $R_{2} \oplus \bar{n}$, with $R_{2} \subseteq R_{1}$ and $\bar{n} \subseteq \bar{m}$.
(iii') $\Gamma \vdash t \oplus \bar{m} \nVdash o b j t . R_{2} \oplus \bar{n}$ if and only if $\Gamma$ contains either $t \not \sharp o b j t . R_{1} \oplus \bar{p}$ or $t \nVdash$ prot. $R_{1} \oplus \bar{p}$, with $R_{2} \subseteq R_{1}$ and $\bar{n} \subseteq \bar{m} \cup \bar{p}$.
(viii') If $\Gamma \vdash \tau_{1} \oplus m \nVdash$ obj t. $R \oplus \bar{n}$, then $\Gamma \vdash \tau_{1} \sharp$ obj t. $R \oplus \bar{n}-m$.
In Lemma 6.6 (Match Weakening), the point (ii) needs to be rewritten as:
(ii) If $\Gamma \vdash \operatorname{prot} .\langle R, n: \sigma\rangle \oplus \bar{m}: *$ or $\Gamma \vdash \operatorname{obj} t .\langle R, n: \sigma\rangle \oplus \bar{m}: *$ can be derived, then $\Gamma, t \nVdash o b j t .\langle R, n: \sigma\rangle \oplus \bar{m} \vdash \sigma: *$.

A new lemma, stating some elementary properties of types with covariant variables and rigid types is necessary.

Lemma 6.12 (Covariant variables and rigid types)
(i) If $t$ is covariant in $\sigma$ and $\Gamma \vdash \sigma: *_{r g d}$ and $\Gamma \vdash \tau_{1} \nVdash \tau_{2}$, then $\Gamma \vdash \sigma\left[\tau_{1} / t\right] \nVdash \sigma\left[\tau_{2} / t\right]$.
(ii) If $\Gamma \vdash \sigma_{1}: *_{r g d}$ and $\Gamma \vdash \sigma_{2}: *_{r g d}$, then $\Gamma \vdash \sigma_{1}\left[\sigma_{2} / t\right]: *_{r g d}$.

Finally, the Subject Reduction for the type assignment system with subsumption has the usual formulation, but needs a more complex proof (reported in Appendix D).

Theorem 6.13 (Subject Reduction, $\lambda \mathcal{O b j} j_{S}^{\oplus}$ ) If $\Gamma \vdash e: \beta$ and $e \rightarrow e^{\prime}$, then $\Gamma \vdash e^{\prime}: \beta$.

## 7 Object reclassification

The natural counterpart of self-extension in class-based languages is known as "(dynamic) object reclassification". This operation allows for the possibility of changing at runtime the class membership of an object while retaining its identity. One major contribution to the development of reclassification features has produced the Java-like Fickle language, in its incremental versions [DDDG01, DDDG02, DDG03].

In this section, we show how the self-inflicted extension primitive provided by our calculus may be used to mimic the mechanisms implemented in Fickle. We proceed, suggestively, by working out a case study: first we write an example in Fickle which illustrates the essential ingredients of the reclassification, then we devise and discuss the possibilities of its encoding in $\lambda \mathcal{O} b j^{\oplus}$.

### 7.1 Reclassification in Fickle

Fickle is an imperative, class-based, strongly-typed language, where classes are types and subclasses are subtypes. It is statically typed, via a type and effect system which turns out to be sound w.r.t. the operational semantics. Reclassification is achieved by dynamically changing the class membership of objects; correspondingly, the type system guarantees that objects will never access non-existing class components.

To develop the example in this section, we will refer to the second version of the language (known as Fickle ${ }_{I I}$ [DDDG02]).

In the Fickle scenario, an abstract class C has two non-overlapping concrete subclasses A and B, where the three classes must be of two different kinds: C is a root class, whereas A and B are state ones. In fact, one finds in root classes, such as C, the declaration of the (private) attributes (a.k.a. fields) and the (public) methods which are common to its state subclasses. On the other hand, state classes, such as A and B, are intended to serve as targets of reclassifications, hence their declaration contains the extra attributes and methods that exclusively belong to each of them.

The reclassification mechanism allows one object in a state class, say A, to become an object of the state class B (or, viceversa, moving from B to A) through the execution of a reclassification expression. The semantics of this operation, which may appear in the body of methods, is that the attributes of the object belonging to the source class are removed, those common to the two classes (which are in C) are retained, and the ones belonging to the target class are added to the object itself, without changing its identity. The same happens to the methods component, with the difference that the abstract methods declared in C (therefore common to A and B) may have different bodies in the two subclasses: when this is the case, reclassifying an object means replacing the bodies of the involved methods, too.

In the example of Figure 3, written in Fickle syntax, we first introduce the class Person, with an attribute to name a person and an abstract method to employ him/her. Then we add two subclasses, to model students and workers, with the following intended meaning. The Student class extends Person via a registration number (id attribute) and by instantiating the employment method. The Worker class extends Person via a remuneration information (salary attribute), a different employment method, and the extra registration method to register as a student. We remark that, in our example, students and workers are mutually exclusive.

The root class Person defines the attributes and methods common to its state subclasses Student and Worker (notice that, being its employment method abstract, the root class itself must be abstract, therefore not supplying any constructor).

```
abstract root class Person extends Object {
    string name;
    abstract void employment(int n) {Person};
}
state class Student extends Person {
    int id;
    Student(string s, int m) { } {name:=s; id:=m};
    void employment(int n) {Person} {this=>Worker; salary:=n};
}
state class Worker extends Person {
    int salary;
    Worker(string s, int n) { } {name:=s; salary:=n};
    void employment(int n) { } {salary:=salary+n};
    void registration(int m) {Person} {this=>Student; id:=m};
    }
```

Figure 3 - Person-Student-Worker example

The classes Student and Worker, being subclasses of a root one (i.e. Person), must be state classes, which means that may be used as targets of reclassifications. Annotations, like \{ \} and \{Person\}, placed before the bodies of the methods, are named effects and are intended to list the root classes of the objects that may be reclassified by invoking those methods: in particular, the empty effect \{ \} cannot cause any reclassification and the non-empty effect \{Person\} allows to reclassify objects of its subclasses. Let us now consider the following program fragment:

1. Person $\mathrm{p}, \mathrm{q}$;
2. $\mathrm{p}:=$ new Student("Alice", 45);
3. $\mathrm{q}:=$ new Worker ("Bob", 27K) ;

After these lines, the variables p and q are bound to a Student and a Worker objects, respectively. To illustrate the key points of the reclassification mechanism, we make Bob become a Student, and Alice first become a Worker and then get a second job:
4. q.registration(57);
5. p.employment (30K) ;
6. p.employment (14K) ;

Line 4 , by sending the registration message to the object q, causes the execution of the reclassification expression this=>Student: before its execution, the receiver $q$ is an object of the Worker class, therefore it contains the salary attribute; after it, q is reclassified into the Student class, hence salary is removed, name is not affected, and the id attribute is added and instantiated with the actual parameter.

Coming to the second object p , belonging to Student and representing Alice, line 5 carries out exactly the opposite operation w.r.t. line 4 , by reclassifying p into the Worker class via the expression this=>Worker, with the result that id is no longer available, name preserves its value, and salary is added and instantiated.

The following line 6 , therefore, selects the employment method from Worker, not from Student as before, because the object $p$ has been reclassified in the meantime.

This latter invocation of employment has the effect of augmenting Alice's income by the actual parameter value, thus allowing us to model a sort of multi-worker.

### 7.2 Desiderata

In this section, we devise the "ideal" behaviour of $\lambda \mathcal{O} b j{ }^{\oplus}$ w.r.t. the reclassification goal, without guaranteeing that the terms we introduce can be typed.

It is apparent that the main tool provided by our calculus to mimic Fickle's reclassification mechanism is the self-extension primitive; precisely, we need a reversible extension functionality, to be used first to extend an object with new methods and later to remove from the resulting object some of its methods. Hence, an immediate solution would rely on a massive use of the self-extension primitive, as follows:

$$
\begin{aligned}
\text { alice } \triangleq\langle n a m e & =\text { "Alice", } \\
r e g= & \lambda s \cdot \lambda m \cdot\langle\langle s \hookleftarrow i d=m\rangle \\
& \leftarrow e m p=\lambda n \cdot s \Leftarrow \operatorname{emp}(n)\rangle, \\
e m p= & \lambda s \cdot \lambda m \cdot\langle\langle\langle s \hookleftarrow s a l=m\rangle \\
& \uplus r e g=\lambda n . s \Leftarrow \operatorname{reg}(n)\rangle \\
& \left.\left.\leftarrow e m p=\lambda s^{\prime} . \lambda p \cdot\left\langle s^{\prime} \oplus s a l=\left(s^{\prime} \Leftarrow s a l\right)+p\right\rangle\right\rangle\right\rangle
\end{aligned}
$$

To model the example of Figure 3 in $\lambda \mathcal{O b j}{ }^{\oplus}$, we have defined the alice object prototype for representing Alice as a person. Now, it can be extended to either a student or a worker via the reg (i.e. registration) or emp (i.e. employment) methods, which are intended to play the role of the Student and Worker constructors of Section 7.1, respectively. We illustrate the behaviour of the former; in fact, alice becomes a student through the reg method, which adds $i d$ to the receiver and overrides the emp method. Therefore, alice $\Leftarrow \operatorname{reg}(45)$ reduces to the following object:

$$
\begin{aligned}
\text { alice }_{S} \triangleq\langle\text { name, reg, } e m p & =\text { as in alice } \\
i d & =45, \\
e m p & =\lambda m . \text { alice } \Leftarrow e m p(m)\rangle
\end{aligned}
$$

In this way, the prototype alice is stored in the body of the novel emp method in the perspective of a reclassification: no matter if a cascade of reg is invoked and emp methods are stacked, because eventually the present version of emp is executed ${ }^{2}$.

Then, alice $_{S}$ can be reclassified into a worker via the invocation of such an emp, which sends to the original alice its former version (i.e. alice's third method). In fact, alice $_{S} \Leftarrow e m p(30 K)$ reduces to:

$$
\begin{aligned}
\text { alice }_{W} \triangleq\langle\text { name, reg, emp } & =\text { as in alice, } \\
\text { sal } & =30 K, \\
r e g & =\lambda m . \operatorname{alice} \Leftarrow \operatorname{reg}(m), \\
e m p & =\lambda s . \lambda n \cdot\langle s \hookleftarrow \operatorname{sal}=(s \Leftarrow s a l)+n\rangle\rangle
\end{aligned}
$$

As the reader can see, the effect of this message is that the methods characterizing a student are removed (by coming back to alice) and those needed by a worker, in turn, extend alice; notice that the novel version of emp models the multi-worker.

To finalize the modeling of Section's 7.1 example in our calculus, alice $_{W}$ 's income may be increased by means of a call to such a version of emp, which has overridden

[^1]alice's third method; i.e. alice $_{W} \Leftarrow \operatorname{emp}(14 K)$ reduces to:
\[

$$
\begin{aligned}
& \text { alice }_{W_{2}} \triangleq\langle\text { name, reg, emp,sal, reg, emp }=\text { as in alice } \\
& \text { sal } \\
&\left.=\left(\text { alice }_{W} \Leftarrow \text { sal }\right)+14 K\right\rangle
\end{aligned}
$$
\]

About typability. The encoding devised in this section may be seen as a reasonable solution to emulate object reclassification in $\lambda \mathcal{O} b j^{\oplus}$; however, the actual free use of the self-extension primitive does not allow us to type the terms introduced.

The point is that the self-variable, representing the receiver object, cannot be used in the body of a method added by self-extension to remove methods, in the attempt to restore the receiver before its extension (it is the case of emp's body, added by the second method reg and, symmetrically, reg's body, added by emp).

We can discuss the issue via the minimal (hence simpler than alice) object:

$$
a n d b a c k \triangleq\left\langle\text { extend }=\lambda s .\left\langle s \leftrightarrow \text { delete }=\lambda s^{\prime} . s\right\rangle\right\rangle
$$

The difficulty to type andback concerns the type returned by the delete method:

$$
\text { andback : prot. }\langle e x t e n d: t \oplus \text { delete, delete }: ?\rangle \oplus \text { extend }
$$

We first observe that the type variable $t$ would not be a suitable candidate for delete, because $t$, within the scope of the above pro binder, is intended to represent the receiver, i.e. in the delete case at hand, the object already extended and therefore containing the delete method.

A second attempt would be typing andback itself with the type returned by delete:

$$
\text { andback }: \tau \triangleq \text { prot. }\langle\text { extend }: t \oplus \text { delete, delete }: \tau\rangle \oplus \text { extend }
$$

That is, the candidate type $\tau$ should satisfy a recursion equation. However, $\lambda \mathcal{O} b j^{\oplus}{ }^{\prime}$ 's recursion mechanisms is not powerful enough to express such a type, hence we are devoting the remaining part of Section 7 to design alternative and typable encodings.

### 7.3 The runtime solution

A first possibility to circumvent the tipability problem arised in Section 7.2 is very plain: at first we extend an object with new methods, and from then we keep just overriding the resulting object, without removing methods from it. That is, the first use of the self-extension leads to object extension, whereas all the following ones to object override. We may then model Figure 3's example via the following prototype:

$$
\begin{aligned}
& \text { alice }{ }^{\prime} \triangleq\langle n a m e=" A l i c e ", \\
& r e g=\lambda s \cdot \lambda m \cdot\langle\langle s \leftrightarrow i d=m\rangle \leftarrow s a l=0\rangle, \\
& e m p=\lambda s \cdot \lambda m \cdot\langle\langle\langle s \leftarrow i d=0\rangle \oplus s a l=m\rangle \\
& \oplus e m p=\lambda s^{\prime} \cdot \lambda n \cdot\left\langle\left\langle s^{\prime} \leftrightarrow i d=0\right\rangle\right. \\
& \left.\left.\left.\leftrightarrow s a l=\left(s^{\prime} \Leftarrow s a l\right)+n\right\rangle\right\rangle\right\rangle
\end{aligned}
$$

As the reader can inspect, in this alternative Alice's encoding the variables representing the host object ( $s$ and $s^{\prime}$ ) are never used in a method body to represent the receiver without the method being defined. This crucial fact holds also for the rightmost sal, where $s^{\prime}$ refers to an object where that method is already available; such a property
can be checked syntactically, hence alice ${ }^{\prime}$ may be given the following type:

$$
\begin{align*}
\text { alice }^{\prime}: \text { prot. }\langle\text { name } & : \text { String, } \\
r e g & : \mathbb{N} \rightarrow t \oplus i d \oplus \text { sal, } \\
e m p & : \mathbb{N} \rightarrow t \oplus i d \oplus \text { sal, }  \tag{1}\\
i d & : \mathbb{N}, \\
\text { sal } & : \mathbb{N}\rangle \oplus \text { name, reg, emp }
\end{align*}
$$

The price to pay for typability is that the objects playing the roles of students and workers will contain more methods than needed (all the methods involved), because no method can be removed. In the present example, when alice' registers as a student, $i d$ and sal are added permanently to the interface, i.e. alice ${ }^{\prime} \Leftarrow \operatorname{reg}(45)$ reduces to:

$$
\begin{aligned}
\text { alice }_{S}^{\prime} \triangleq\langle\text { name, reg, emp } & =\text { as in alice }{ }^{\prime}, \\
i d & =45, \\
\text { sal } & =0\rangle
\end{aligned}
$$

Therefore, the type system will not detect type errors related to uncorrect method calls. In fact, alice ${ }_{S}^{\prime}$ is intended to represent a student, but in practice we will have to distinguish between students and workers via the runtime answers to the $i d$ and sal (representing students' and workers' attributes, respectively) method invocations: non-zero values (such as 45 , returned by $i d$ ) are informative of genuine attributes, while zero values (returned by sal) tell us that the corresponding attribute is not significant. This solution is reminiscent of an approach to reclassification via wide classes, requiring runtime tests to diagnose the presence of fields [Ser99].

We proceed by reclassifying alice ${ }_{S}^{\prime}$ into a worker; alice $_{S}^{\prime} \Leftarrow \operatorname{emp}(30 K)$ reduces to ${ }^{3}$ :

$$
\begin{aligned}
\text { alice }_{W}^{\prime} \triangleq\langle\text { name, reg } & =\text { as in } \text { alice }^{\prime}, \\
i d & =0, \\
s a l & =30 K, \\
e m p & =\lambda s \cdot \lambda m \cdot\langle\langle s \leftarrow i d=0\rangle \\
&
\end{aligned}
$$

The consequence of this call to (the original) emp is that id and sal swap their role, thus making effective the reclassification, and a new version of emp is embedded in the interface. Notice that such a novel emp (incrementing the salary sal) works correctly not only with the usual multi-worker operation alice $_{W}^{\prime} \Leftarrow e m p(14 K)$, reducing to:

$$
\begin{aligned}
\text { alice }_{W_{2}}^{\prime} \triangleq\langle\text { name, reg, emp } & =\text { as in alice } W_{W}^{\prime} \\
i d & =0, \\
\text { sal } & \left.=\left(\text { alice }_{W}^{\prime} \Leftarrow \text { sal }\right)+14 K\right\rangle
\end{aligned}
$$

but also in the case of a further reclassification of alice ${ }_{W}^{\prime}$ into a student, because setting ex-novo a salary is equivalent to adding it to the zero value stored by reg.

Finally, a couple of remarks about the relationship of the two emp versions with the type (1). First, the fact that the overridden emp (i.e. the one belonging to alice') extends the receiver via $i d$ and sal but overrides itself is clearly expressed by its type $\mathbb{N} \rightarrow t \oplus i d \oplus$ sal. Second, the redundant $i d$ version contained by the overriding emp (i.e. the one that appears in alice ${ }_{W}^{\prime}$ ) is hence necessary to respect such a type.

[^2]
### 7.4 Creating new objects

A second way to achieve the possibility to remove methods from an object is by creating new objects. To illustrate such an approach, we pick out the following object:

$$
a n d b a c k^{\prime} \triangleq\left\langle\text { extend }=\lambda s .\left\langle\text { extend }=\lambda s^{\prime} . s^{\prime}, \text { delete }=\lambda s^{\prime} . s\right\rangle\right\rangle
$$

which models the same behavior of the minimal andback, introduced in Section 7.2 to enlighten the typability problem that we want to encompass. In the present case, the method delete is allowed by the type system to return its prototype object (represented by the variable $s$ ), because such a method belongs to a completely new object, not to an object which has extended its prototype (as it was in Section 7.2):
andback ${ }^{\prime}: \tau^{\prime} \triangleq$ prot. $\left\langle\right.$ extend:prot $t^{\prime} .\left\langle\right.$ extend: $t^{\prime}$, delete $\left.: t\right\rangle \oplus$ extend, delete $\rangle \oplus$ extend
The reader may observe how the type $\tau^{\prime}$ reflects the explanation given above: a new object is generated via the extend method and represented by $t^{\prime}$; within such an object, the delete method refers to the prototype object, represented by $t$.

We apply the idea to our working example; combining the self-extension primitive with the generation of new objects leads to a third Alice's representation:

$$
\begin{aligned}
& a_{l i c e} " \triangleq\langle n a m e= \text { "Alice", } \\
& r e g= \lambda s \cdot \lambda m \cdot\langle n a m e=s \Leftarrow n a m e, \\
& \quad i d=m, \\
&e m p=\lambda n \cdot\langle s \leftarrow \text { sal }=0\rangle \Leftarrow e m p(n)\rangle, \\
& e m p= \lambda s \cdot \lambda m \cdot\langle\langle s \hookleftarrow \operatorname{sal}=m\rangle \\
&\left.\left.\hookleftarrow e m p=\lambda s^{\prime} . \lambda n \cdot\left\langle s^{\prime} \oplus s a l=\left(s^{\prime} \Leftarrow s a l\right)+n\right\rangle\right\rangle\right\rangle
\end{aligned}
$$

The novelty of the present solution amounts to the fact that the reg method creates a new object from scratch, equipped with three methods: the first one copies the name value from its prototype, the second method sets the $i d$ attribute, and, the key point, the emp method is allowed to refer back to the prototype object to prepare for a potential worker reclassification. As argued above, this latter method is typable, conversely to its version in alice (Section 7.2), because it is not added by self-extension, but belongs to a different object, created ex-novo. In the end, the alice ${ }^{\prime \prime}$ prototype object can type-checked against the following type ${ }^{4}$ :

$$
\begin{aligned}
& \text { alice }{ }^{\prime \prime}: \rho \triangleq \text { prot. }\langle\text { name : String, } \\
& \text { reg : } \mathbb{N} \rightarrow \text { prot }^{\prime} .\langle\text { name : String }, \\
& i d: \mathbb{N} \text {, } \\
& e m p: \mathbb{N} \rightarrow t \oplus s a l\rangle \oplus n a m e, i d, e m p, \\
& \text { emp : } \mathbb{N} \rightarrow t \oplus \text { sal, } \\
& \text { sal : } \mathbb{N}\rangle \oplus \text { name, reg, emp }
\end{aligned}
$$

where it is apparent that both the emp versions add sal to alice"'s interface. Then, the outcome of Alice's registration, alice ${ }^{\prime \prime} \Leftarrow \operatorname{reg}(45)$, is the following:

$$
\begin{aligned}
& \text { alice } e_{S}^{\prime \prime} \triangleq \quad\left\langle n a m e=\text { alice }^{\prime \prime} \Leftarrow \text { name },\right. \\
& i d=45 \text {, } \\
& \left.e m p=\lambda m .\left\langle\text { alice }{ }^{\prime \prime} \leftrightarrow s a l=0\right\rangle \Leftarrow e m p(m)\right\rangle \\
& \text { alice }{ }_{S}^{\prime \prime} \text { : prot }{ }^{\prime}{ }^{\langle } \text {name : String, } \\
& \text { id : } \mathbb{N} \text {, } \\
& \text { emp : } \mathbb{N} \rightarrow \rho \oplus \text { sal }\rangle \oplus \text { name, } i d, e m p
\end{aligned}
$$

[^3]One can see in this latter type that，coherently，the emp method adds sal to the prototype alice＂．We observe also that，in emp＇s body，a＂local＂version of sal is added on the fly to the receiver（alice＂，in the case）before the call to the outer emp．This is necessary to guarantee the correctness of the protocol in the event of a call to alice ${ }^{\prime \prime}$＇s emp before than reg（an example that we do not detail here）：emp overrides itself， thus losing from then the possibility to set the salary from scratch（see the alice＂ term），which must be hence incremented starting from zero．

The chance to send $e m p$ to the prototype alice ${ }^{\prime \prime}$ ，via the alice ${ }_{S}^{\prime \prime} \Leftarrow e m p(30 K)$ call， is crucial for the reclassification，giving in fact the following outcome：

$$
\begin{aligned}
& \text { alice } e_{W}^{\prime \prime} \triangleq \quad \text { _name, reg }=\text { as in alice }{ }^{\prime \prime} \text {, } \\
& \text { sal }=30 K \text {, } \\
& e m p=\lambda s . \lambda m \cdot\langle s \hookleftarrow s a l=(s \Leftarrow s a l)+m\rangle\rangle \\
& \text { alice }{ }_{W}^{\prime \prime} \text { : prot.〈name : String, } \\
& \text { reg : } \mathbb{N} \rightarrow \text { prot }{ }^{\prime} .\langle\text { name : String }, \\
& i d: \mathbb{N} \text {, } \\
& e m p: \mathbb{N} \rightarrow t\rangle \oplus n a m e, i d, e m p \\
& \text { sal : } \mathbb{N} \text {, } \\
& \text { emp : } \mathbb{N} \rightarrow t\rangle \oplus \text { name, reg, sal, emp }
\end{aligned}
$$

where the presence of the salary in the new interface is reflected by both emp＇s types．
We end by adding the usual second job to Alice，through the alice $e_{W}^{\prime \prime} \Leftarrow e m p(14 K)$ call，which reduces to the following object，whose type is the same of alice ${ }_{W}^{\prime \prime}$ ：

$$
\begin{aligned}
\text { alice }_{W_{2}}^{\prime \prime} \triangleq\langle n a m e, \text { reg, emp } & =\text { as in alice }{ }_{W}^{\prime \prime}, \\
\text { sal } & \left.=\left(\text { alice }_{W}^{\prime \prime} \Leftarrow s a l\right)+14 K\right\rangle
\end{aligned}
$$

Discussion．It is apparent that the opposite reclassification direction（Alice first becoming a worker and then a student）would produce terms behaviourally equivalent to alice ${ }_{W}^{\prime \prime}$ and alice ${ }_{S}^{\prime \prime}$ ，even though not syntactically identical．

We remark also that in fact a couple of choices is already feasible，if one decides to combine self－extensions and new objects：in principle，there is no reason to prefer the encoding that we have illustrated to the symmetrical one（simpler，in the case），where students are modeled via self－extensions and workers through new objects．

To conclude，the reader might wonder about the asymmetry of the solution developed in this section，as students are managed via new objects and workers through self－extensions．Actually，in Section 7.2 we have shown that modeling the reclassification by means of the sole self－extension mechanism leads to non－typable terms．On the opposite side，it is always possible to encode the reclassification via only new objects（to manage also workers），without the need of the self－extension：

$$
\begin{aligned}
& \text { alice }{ }^{\prime \prime \prime} \triangleq \text { 〈name }=\text { "Alice", } \\
& r e g=\lambda s . \lambda m \cdot\langle n a m e=s \Leftarrow \text { name }, \\
& i d=m \text {, } \\
& e m p=\lambda n . s \Leftarrow e m p(n)\rangle, \\
& e m p=\lambda s \cdot \lambda m \cdot\langle n a m e=s \Leftarrow n a m e, \\
& s a l=m, \\
& e m p=\lambda s^{\prime} \cdot \lambda n \cdot\left\langle s^{\prime} \leftrightarrow s a l=\left(s^{\prime} \Leftarrow s a l\right)+n\right\rangle, \\
& r e g=\lambda p . s \Leftarrow \operatorname{reg}(p)\rangle\rangle
\end{aligned}
$$

Summarizing, in this section we have tried to push the self-extension, which is the technical novelty of this paper, to its limit (i.e. typability). We believe that such an effort is interesting per se; moreover, the "mixed" solution which arises from our investigation leads to a more compact encoding, giving the benefit of code reuse.

## 8 Related work

Several efforts have been carried out in recent years with an aim similar to that of our work, namely for the sake of providing static type systems for object-oriented languages that change at runtime the behaviour of objects. In this section, first we discuss the approaches in the literature by considering separately the two main categories of prototype-based and class-based languages, afterwards we survey the relationship between object extension and object subsumption.

### 8.1 In prototype-based languages

A few works consider the problem of defining static type disciplines for JavaScript, a prototype-based, dynamically typed language where objects can be modified at runtime and errors caused by calls to undefined methods may occur.

Zhao in [Zha12] presents a static type inference algorithm for a fragment of JavaScript and suggests two type disciplines for preventing undefined method calls. Similarly to the $\lambda \mathcal{O} b j^{\oplus}$ calculus, JavaScript provides self-inflicted extension; to deal with this feature, some ideas shared with our approach are adopted, namely $i$ ) the distinction between pro-types and obj-types, $i i$ ) the distinction between "available" and "reserved" methods, and $i i i$ ) the mechanisms to mark the migration of a method from reserved to available. On the other hand, the main differences or extra features w.r.t. our work are the following: a) JavaScript allows strong update, i.e. overriding a method with a different type, and the type system accommodates, in a limited way, this functionality; $b$ ) the types are defined by means of a set of subtyping constraints; $c)$ the syntax is completely different.

Chugh and co-workers propose in [CHJ12] a static type system for quite a rich subset of JavaScript. The considered features are imperative updates (i.e. updates that change the set of methods of an object by adding and also subtracting methods) and arrays, which in JavaScript can be homogeneous (when all the elements have the same type) but also heterogeneous, like tuples. As the syntax makes no distinction between these two kinds of arrays, to form the correct type can be challenging. In order to deal with subtyping and inheritance, the authors further elaborate our idea of splitting the list of methods into reserved and available parts.

Vouillon presents in [Vou01] a prototype-based calculus containing the "objectview" mechanism, which permits to change the interface between an object and the environment, thus allowing an object to hide part of its methods in some context. As in our work, the author defines a distinction between pro-types and obj-types.

### 8.2 In class-based languages

The typical setting where class-based languages are investigated is a Java-like environment. In the previous Section 7 we have considered object reclassification, a feature introduced in the class-based paradigm, and we have experimented with modeling in $\lambda \mathcal{O b j}{ }^{\oplus}$ the reclassification mechanism implemented in Fickle [DDDG02]. We complete
now the survey of the involved related work by presenting other contributions that fall in the same class-based category.

Cohen and Gil's work [CG09], about the introduction of object evolution into statically typed languages, is much related to reclassification, because evolution is a restriction of reclassification, by which objects may only gain, but never lose their capabilities (hence it may be promptly mimicked in $\lambda \mathcal{O} b j^{\oplus}$ ). An evolution operation (which may be of three non-mutually exclusive variants, based respectively on inheritance, mixins, and shakeins) takes at runtime an instance of one class and replaces it with an instance of a selected subclass. The monotonicity property granted by such a kind of dynamic change makes easier to maintain static type-safety than in general reclassification. In the end, the authors experiment with an implementation of evolution in Java, based on the idea of using a forward pointer to a new memory address to support the objects which have evolved, starting from the original non-evolved object.

Monpratarnchai and Tamai [MT08] introduce an extension of Java named EpsilonJ, featuring role modeling (that is, a set of roles to represent collaboration carried out in that context, e.g. between an employer and its employees) and object adaptation (that is, a dynamic change of role, to partecipate in a context by assuming one of its roles). Dynamically acquired methods obtained by assuming roles have to be invoked by means of down-casting, which is a type unsafe operation. Later, Kamina and Tamai [KT10] introduce an extension of Java named NextEJ, to combine the object-based adaptation mechanisms of EpsilonJ and the object-role binding provided by context-oriented languages. In fact, the authors model in NextEJ the context activation scope, adopted from the latter languages, and prove that such a mechanism is type sound by using a small calculus which formalizes the core features of NextEJ.

Ressia and co-workers $\left[\mathrm{RGN}^{+} 14\right]$ introduce a new form of inheritance called talents. A talent is an object belonging to a standard class, named Talent, which can be acquired (via a suitable acquire primitive) by any object, which is then adapted. The crucial operational characteristics of talents are that they are scoped dynamically and that their composition order is irrelevant. However, when two talents with different implementations of the same method are composed a conflict arises, which has to be resolved either through aliasing (the name of the method in a talent is changed) or via exclusion (the method is removed from a talent before composition).

### 8.3 Object extension vs. subsumption

Several calculi proposed in the literature combine object extension with object subsumption. Beside of the peculiar technicalities of those proposals, they all share the principle of avoiding (type incompatible) object extensions in presence of a (limited) form of object subsumption.

Riecke and Stone in [RS98] present a calculus where it is possible to first subsume (forget) an object component, and then re-add it again with a type which may be incompatible with the forgotten one. In order to guarantee the soundness of the type system, method dictionaries are used inside objects with the goal of linking correctly method names and method bodies.

Ghelli in [Ghe02] pursues the same freedom (of forgetting a method and adding it again with a different incompatible type) by introducing a context-dependent behaviour of objects called object role. Ghelli introduces a role calculus, which is a minimal extension of Abadi-Cardelli's $\varsigma$-calculus, where an object is allowed to change
dynamically identity while keeping static type checking. Vouillon's "view" mechanism [Vou01], see Section 8.1, can also be interpreted as a a kind of role.

Approaches to subsumption similar to the one presented in this work can be found in [FM95, Liq97, BBDL97, Rém98]. In [Liq97], an extension of Abadi-Cardelli's Object Calculus is presented; roughly speaking, we can say that pro-types and obj-types in the present article correspond to "diamond-types" and "saturated-types" in that work. Similar ideas can be found in [Rém98], although the type system there presented permits also a form of self-inflicted extension. However, in that type system, a method $m$ performing a self-inflicted extension needs to return a rigid object whose type is fixed in the declaration of the body of $m$. As a consequence, the following expressions would not be typable in that system:

$$
\begin{aligned}
& \left\langle\left\langle p \Leftarrow n e w_{m}=\ldots\right\rangle \Leftarrow a d d_{c o l}\right\rangle \Leftarrow n e w_{m} \\
& \left\langle\left\langle p \Leftarrow a d d_{\text {col }}\left\langle\oplus n e w_{m}=\ldots\right\rangle\right.\right.
\end{aligned}
$$

Another type system for the $\lambda \mathcal{O} b j$ calculus is presented in [BBDL97]; such a type system uses a refined notion of subtyping that allows to type also binary methods.

\end{aligned}
$$

## C Soundness of the Type System $\lambda \mathcal{O} b j^{\oplus}$

Lemma C. 1 (Sub-derivation)
(i) If $\Delta$ is a derivation of $\Gamma_{1}, \Gamma_{2} \vdash \mathcal{A}$, then there exists a sub-derivation $\Delta^{\prime} \subseteq \Delta$ of $\Gamma_{1} \vdash o k$.
(ii) If $\Delta$ is a derivation of $\Gamma_{1}, x: \sigma, \Gamma_{2} \vdash \mathcal{A}$, then there exists a sub-derivation $\Delta^{\prime} \subseteq \Delta$ of $\Gamma_{1} \vdash \sigma: *$.
(iii) If $\Delta$ is a derivation of $\Gamma_{1}, t \not \sharp \tau, \Gamma_{2} \vdash \mathcal{A}$, then there exists a sub-derivation $\Delta^{\prime} \subseteq \Delta$ of $\Gamma_{1} \vdash \tau: *$.

The three points are proved, separately, by structural induction on the derivation $\Delta$.
(i) The only cases where the inductive hypothesis cannot be applied are the cases where the last rule in $\Delta$ is a context rule (that is, the only kind of rule that can increase the context) and $\Gamma_{2}$ is empty. In these cases the thesis coincides with the hypothesis. In all the other cases the thesis follows immediately by an application of the inductive hypothesis.
(ii) As in point (i), either we conclude immediately by inductive hypothesis or it is the case that $\Gamma_{2}$ is empty and the last rule in $\Delta$ is a context rule. In this latter case the last rule in $\Delta$ is necessarily a (Cont $-x$ ) rule deriving $\Gamma_{1}, x: \sigma \vdash o k$, and the first premise of this rule coincides with the thesis.
(iii) The proof works similarly to point (ii).

Lemma C. 2 (Weakening)
(i) If $\Gamma_{1}, \Gamma_{2} \vdash \mathcal{A}$ and $\Gamma_{1}, \mathcal{C}, \Gamma_{2} \vdash o k$, then $\Gamma_{1}, \mathcal{C}, \Gamma_{2} \vdash \mathcal{A}$.
(ii) If $\Gamma_{1} \vdash \mathcal{A}$ and $\Gamma_{1}, \Gamma_{2} \vdash o k$, then $\Gamma_{1}, \Gamma_{2} \vdash \mathcal{A}$.
(i) By structural induction on the derivation $\Delta$ of $\Gamma_{1}, \Gamma_{2} \vdash \mathcal{A}$. If the last rule in $\Delta$ has the context in the conclusion identical to the context in the premise(s), then it is possible to apply the inductive hypothesis, thus deriving almost immediately the goal. In the other cases, if the last rule in $\Delta$ is a $($ Cont $-x)$ or $(C o n t-t)$ rule, then the proof is trivial, since the second hypothesis coincides with the thesis. The remaining cases concern the (Type-Pro), (Abs), (Extend) and (Override) rules, which require a more careful treatment. We detail here only the proof for (Type-Pro), since the other rules are handled in a similar way.

In the (Type-Pro) case, the hypothesis $\Gamma_{1}, \Gamma_{2} \vdash \operatorname{prot} .\langle R, m: \sigma\rangle: *$ follows from:

$$
\begin{equation*}
\Gamma_{1}, \Gamma_{2}, t \not \sharp \text { prot. } R \vdash \sigma: * \tag{2}
\end{equation*}
$$

Let us briefly remark that if the statement $\mathcal{C}$ of the second hypothesis is equal to $t \not \sharp \tau$, for some type $\tau$, then it is convenient to $\alpha$-convert the type prot. $\langle R, m: \sigma\rangle$ to avoid clash of variables. In any case, by Lemma C.1.(iii) (Sub-derivation), there exists a sub-derivation of $\Delta$ deriving $\Gamma_{1}, \Gamma_{2} \vdash$ prot. $R: *$, from which, by inductive hypothesis, $\Gamma_{1}, \mathcal{C}, \Gamma_{2} \vdash$ prot. $R: *$ and in turn, via the $($ Cont $-t)$ rule, $\Gamma_{1}, \mathcal{C}, \Gamma_{2}, t \nVdash$ prot. $R \vdash$ ok. By using (2) and the inductive hypothesis, we deduce $\Gamma_{1}, \mathcal{C}, \Gamma_{2}, t \not \sharp p r o t . R \vdash \sigma: *$. Finally we have the thesis via the (Type-Pro) rule.
(ii) By induction on the length of $\Gamma_{2}$; the proof uses the previous point (i) and Lemma C.1.(i) (Sub-derivation).

Lemma C. 3 (Well-formed object-types)
(i) $\Gamma \vdash$ prot. $R \oplus \bar{m}: *$ if and only if $\Gamma \vdash$ prot. $R: *$ and $\bar{m} \subseteq \bar{R}$.
(ii) $\Gamma \vdash t \oplus \bar{m}: *$ if and only if $\Gamma$ contains $t \nVdash$ prot. $R \oplus \bar{n}$, with $\bar{m} \subseteq \bar{R}$.

Point (i) is immediately proved by inspection on the rules for well-formed types and matching. Point (ii) is proved by inspection on the rules for well-formed contexts, well-formed types and matching.

Notice that in the following proofs often we will not refer explicitly to the previous lemmas, thus considering obvious their application.

Proposition C. 4 (Matching is well-formed)

$$
\text { If } \Gamma \vdash \tau_{1} \nVdash \tau_{2} \text {, then } \Gamma \vdash \tau_{1}: * \text { and } \Gamma \vdash \tau_{2}: * \text {. }
$$

By structural induction on the derivation $\Delta$ of $\Gamma \vdash \tau_{1} \sharp \tau_{2}$. The premises of the (Match-Pro) rule coincide with the thesis. If the last rule in $\Delta$ is (Match-t), we conclude by using its premises and Lemma C.3.(ii) (Well-formed object-types). If the last rule in $\Delta$ is (Match-Var), then the judgment $\Gamma_{1}, t \nVdash \rho, \Gamma_{2} \vdash t \oplus \bar{m} \nVdash \tau_{2}$ is derived from $\Gamma_{1}, t \not \sharp \rho, \Gamma_{2} \vdash \rho \oplus \bar{m} \sharp \tau_{2}$. By inductive hypothesis $\tau_{2}$ is well-formed and $\Gamma_{1}, t \not \sharp \rho, \Gamma_{2} \vdash \rho \oplus \bar{m}: *$. By inspecting the (Cont-t) rule, $\rho$ must be in the form prot. $R \oplus \bar{n}$, and by Lemma C.3.(i) (Well-formed types) it holds $\bar{m} \subseteq \bar{R}$. We can now conclude $\Gamma_{1}, t \nVdash \rho, \Gamma_{2} \vdash t \oplus \bar{m}: *$ via Lemma C.3.(ii) (Well-formed object-types).

Lemma C. 5 (Matching)
(i) $\Gamma \vdash$ prot. $R_{1} \oplus \bar{m} \nVdash \tau_{2}$ if and only if $\Gamma \vdash$ prot. $R_{1} \oplus \bar{m}: *$ and $\Gamma \vdash \tau_{2}: *$ and $\tau_{2} \equiv$ prot. $R_{2} \oplus \bar{n}$, with $R_{2} \subseteq R_{1}$ and $\bar{n} \subseteq \bar{m}$.
(ii) $\Gamma \vdash \tau_{1} \nVdash t \oplus \bar{n}$ if and only if $\Gamma \vdash \tau_{1}: *$ and $\tau_{1} \equiv t \oplus \bar{m}$, with $\bar{n} \subseteq \bar{m}$.
(iii) $\Gamma \vdash t \oplus \bar{m} \not \sharp$ prot. $R_{2} \oplus \bar{n}$ if and only if $\Gamma$ contains $t \not \sharp$ prot. $R_{1} \oplus \bar{p}$, with $R_{2} \subseteq R_{1}$ and $\bar{n} \subseteq \bar{m} \cup \bar{p}$.
(iv) (Reflexivity) If $\Gamma \vdash \rho: *$ then $\Gamma \vdash \rho \nVdash \rho$.
(v) (Transitivity) If $\Gamma \vdash \tau_{1} \sharp \rho$ and $\Gamma \vdash \rho \nVdash \tau_{2}$, then $\Gamma \vdash \tau_{1} \sharp \tau_{2}$.
(vi) (Uniqueness) If $\Gamma \vdash \tau_{1} \not \sharp$ prot. $\left\langle R_{1}, m: \sigma_{1}\right\rangle$ and $\Gamma \vdash \tau_{1} \sharp$ prot. $\left\langle R_{2}, m: \sigma_{2}\right\rangle$, then $\sigma_{1} \equiv \sigma_{2}$.
(vii) If $\Gamma \vdash \tau_{1} \nVdash \tau_{2}$ and $\Gamma \vdash \tau_{2} \oplus m: *$, then $\Gamma \vdash \tau_{1} \oplus m \nVdash \tau_{2} \oplus m$.
(viii) If $\Gamma \vdash \tau_{1} \oplus m \nVdash$ prot. $R \oplus \bar{n}$, then $\Gamma \vdash \tau_{1} \not \sharp$ prot. $R \oplus \bar{n}-m$.
(ix) If $\Gamma \vdash \rho \oplus m: *$, then $\Gamma \vdash \rho \oplus m \nVdash \rho$.
(i) (ii) (iii) The thesis is immediate by inspection on the matching rules.
(iv) By cases on the form of the object-type $\rho$. The thesis can be derived immediately using either the (Match-Pro) rule or the (Match-t) one.
(v) By cases on the forms of $\tau_{1}, \tau_{2}, \rho$, using the points (i), (ii), (iii) above. If $\tau_{1} \equiv$ prot. $R \oplus \bar{m}$, we conclude by a triple application of point (i). If $\tau_{2} \equiv t \oplus \bar{n}$, we conclude by three applications of point (ii). If $\tau_{1} \equiv t \oplus \bar{m}$ and $\tau_{2} \equiv \operatorname{prot} . R \oplus \bar{n}$, we conclude by reasoning on the form of $\rho$, using all the points (i), (ii), (iii).
(vi) By cases on the form of $\rho$, using either point (i) or point (iii).
(vii) By cases on the form of $\tau_{1}$. If $\tau_{1} \equiv \operatorname{prot.} R \oplus \bar{m}$, we have the thesis by point (i) and Lemma C.3.(i) (Well-formed object-types). If $\tau_{1} \equiv t \oplus \bar{m}$, we reason by cases on the form of $\tau_{2}$ : if $\tau_{2} \equiv$ prot. $R \oplus \bar{n}$, then we have the thesis by point (iii) and the validity of the thesis for pro-types; if $\tau_{2} \equiv t \oplus \bar{n}$, then we have the thesis by point (ii).
(viii) By cases on the form of $\tau_{1}$, using either point (i) or point (iii).
(ix) By cases on the form of $\rho$, using either point (i) or point (ii) and Lemma C.3.(ii) (Well-formed object-types).

Lemma C. 6 (Match Weakening)
(i) If $\Gamma_{1}, t \nVdash \rho, \Gamma_{2} \vdash \mathcal{A}$ and $\Gamma_{1} \vdash \tau \nVdash \rho$, with $\tau$ a pro-type, then $\Gamma_{1}, t \nVdash \tau, \Gamma_{2} \vdash \mathcal{A}$.
(ii) If $\Gamma \vdash \operatorname{prot} .\langle R, n: \sigma\rangle \oplus \bar{m}: *$, then $\Gamma, t \not \sharp \operatorname{prot} .\langle R, n: \sigma\rangle \oplus \bar{m} \vdash \sigma: *$.
(i) By structural induction on the derivation $\Delta$ of $\Gamma_{1}, t \not \sharp \rho, \Gamma_{2} \vdash \mathcal{A}$.

The only case where the inductive hypothesis cannot be applied is when $\Gamma_{2}$ is empty and the last rule in $\Delta$ is a rule increasing the length of the context, i.e. the $(C o n t-t)$ rule. In fact, $\Gamma, t \not \sharp \rho \vdash o k$ is derived from $t \notin \operatorname{Dom}(\Gamma)$; on the other hand, from the second hypothesis and Lemma C. 4 we have also that $\Gamma_{1} \vdash \tau: *$, hence we may derive the thesis using the same (Cont-t) rule.

For all the other cases but one the application of the inductive hypothesis and the derivation of the thesis is immediate, since the last rule in $\Delta$ does not use the hypothesis $t \not \sharp \rho$ in the context. The only rule that can use this hypothesis is (Match-Var): in such a case $\Gamma_{1}, t \sharp \rho, \Gamma_{2} \vdash t \oplus \bar{m} \not \sharp v$ is derived from the premise $\Gamma_{1}, t \sharp \rho, \Gamma_{2} \vdash$ $\rho \oplus \bar{m} \sharp \sharp v$. By inductive hypothesis, we have $\Gamma_{1}, t \not \sharp \tau, \Gamma_{2} \vdash \rho \oplus \bar{m} \sharp \Downarrow v$. Moreover, from $\Gamma_{1} \vdash \tau \sharp \rho$ and the Weakening Lemma C.2, we derive $\Gamma_{1}, t \nVdash \tau, \Gamma_{2} \vdash \tau \sharp \rho$, from which, by Lemma C.5.(vii), $\Gamma_{1}, t \not \sharp \tau, \Gamma_{2} \vdash \tau \oplus \bar{m} \not \sharp \rho \oplus \bar{m}$. Finally, by transitivity of matching (Lemma C.5.(v)), we have $\Gamma_{1}, t \nVdash \tau, \Gamma_{2} \vdash \tau \oplus \bar{m} \sharp v$, and by an application of the (Match-Var) rule we obtain the thesis.
(ii) First observe that there exists $R_{1} \subseteq R$ such that $\Gamma, t \nVdash$ prot. $R_{1} \vdash \sigma: *$. In fact, by Lemma C.3.(i) (Well-formed object-types), we have $\Gamma \vdash \operatorname{prot} .\langle R, n: \sigma\rangle: *$, that can only be derived by an application of the (Type-Pro) rule; therefore, we have either our goal or $\Gamma, t \not \sharp$ prot. $\left\langle R_{2}, n: \sigma\right\rangle \vdash \alpha: *$ for a suitable $R_{2}$ such that $R \equiv\left\langle R_{2}, p: \alpha\right\rangle$. From Lemma C.1.(iii) (Sub-derivation) follows that $\Gamma \vdash \operatorname{prot} .\left\langle R_{2}, n: \sigma\right\rangle: *$, hence we may conclude the existence of $R_{1}$.

Now, from $\Gamma, t \nVdash p r o t . R_{1} \vdash \sigma: *$, by using Lemma C.1.(iii) (Sub-derivation), the (Match-Pro) rule and point (i), we have the thesis.

## Proposition C. 7 (Substitution)

(i) If $\Gamma_{1}, x: \sigma, \Gamma_{2} \vdash \mathcal{A}$ and $\Gamma_{1} \vdash e: \sigma$, then $\Gamma_{1}, \Gamma_{2} \vdash \mathcal{A}[e / x]$.
(ii) If $\Gamma_{1}, t \nVdash \tau, \Gamma_{2}, \Gamma_{3} \vdash \mathcal{A}$ and $\Gamma_{1}, t \nVdash \tau, \Gamma_{2} \vdash \rho \sharp \tau$, then $\Gamma_{1}, t \nVdash \tau, \Gamma_{2}, \Gamma_{3}[\rho / t] \vdash$ $\mathcal{A}[\rho / t]$.
(iii) If $\Gamma_{1}, t \nVdash \tau, \Gamma_{2} \vdash \mathcal{A}$ and $\Gamma_{1} \vdash \rho \nVdash \tau$, then $\Gamma_{1}, \Gamma_{2}[\rho / t] \vdash \mathcal{A}[\rho / t]$.
(i) By induction on the derivation $\Delta$ of $\Gamma_{1}, x: \sigma, \Gamma_{2} \vdash \mathcal{A}$. The only situation where the inductive hypothesis cannot be immediately applied is when the last rule in $\Delta$ is $(C o n t-x)$. In such a case $\Gamma_{1}, x: \sigma \vdash o k$ is derived from $\Gamma_{1} \vdash \sigma: *$, from which, by Lemma C.1.(i) (Sub-derivation), we have the thesis.

All the remaining rules can be easily managed by applying the inductive hypothesis, apart from the case where the last rule in $\Delta$ is (Var) and the variable $x$ coincides with the one dealt with by the rule. In this case the conclusion $\Gamma_{1}, x: \sigma, \Gamma_{2} \vdash x: \sigma$ derives from the premise $\Gamma_{1}, x: \sigma, \Gamma_{2} \vdash o k$ and so $\Gamma_{1}, \Gamma_{2} \vdash o k$ by induction. By the second hypothesis $\Gamma_{1} \vdash e: \sigma$ and Lemma C. 2 (Weakening), we deduce $\Gamma_{1}, \Gamma_{2} \vdash e: \sigma$.
(ii) By induction on the derivation $\Delta$ of $\Gamma_{1}, t \not \sharp \tau, \Gamma_{2}, \Gamma_{3} \vdash \mathcal{A}$. As in the previous point, the only case where the inductive hypothesis cannot be applied is when the last rule in $\Delta$ is a context rule; in this case the hypothesis coincides with the thesis.

About the remaining rules, the only non-trivial case is when the last rule in $\Delta$ is (Match-Var) (the only rule that can use the judgment $t \not \sharp \tau$ of the context) and the type variable $t$ coincides with the one dealt with by the rule. In this case the conclusion $\Gamma_{1}, t \nVdash \tau, \Gamma_{2}, \Gamma_{3} \vdash t \oplus \bar{m} \nVdash \tau_{2}$ derives from the premise $\Gamma_{1}, t \not \sharp \tau, \Gamma_{2}, \Gamma_{3} \vdash$ $\tau \oplus \bar{m} \nVdash \tau_{2}$; then, by inductive hypothesis, $\Gamma_{1}, t \not \sharp \tau, \Gamma_{2}, \Gamma_{3}[\rho / t] \vdash\left(\tau \oplus \bar{m} \nVdash \tau_{2}\right)[\rho / t]$. By the side condition on (Cont-t), $t$ cannot be free in $\tau$ and, by Lemma C. 5 (i),
neither in $\tau_{2}$; hence, the above judgment can be written as $\Gamma_{1}, t \not \sharp \tau, \Gamma_{2}, \Gamma_{3}[\rho / t] \vdash$ $\tau \oplus \bar{m} \not \sharp \tau_{2}$. On the other hand, from the second hypothesis $\Gamma_{1}, t \nVdash \tau, \Gamma_{2} \vdash \rho \sharp \tau$ we can derive $\Gamma_{1}, t \not \sharp \tau, \Gamma_{2}, \Gamma_{3}[\rho / t] \vdash \rho \oplus \bar{m} \sharp \tau \oplus \bar{m}$ by Lemma C.2.(ii) (Weakening) and Lemma C.5.(vii), and from the transitivity of matching (Lemma C.5.(v)) we can conclude $\Gamma_{1}, t \nVdash \tau, \Gamma_{2}, \Gamma_{3}[\rho / t] \vdash \rho \oplus \bar{m} \nVdash \tau_{2}$.
(iii) By the previous point we can derive $\Gamma_{1}, t \not \sharp \tau, \Gamma_{2}[\rho / t] \vdash \mathcal{A}[\rho / t]$. Now, via an immediate induction, one can prove that if $\Gamma_{1}, t \nVdash \tau, \Gamma_{2} \vdash \mathcal{A}$ and $t$ is not free in $\Gamma_{2}$ nor in $\mathcal{A}$, then $\Gamma_{1}, \Gamma_{2} \vdash \mathcal{A}$. The thesis follows immediately from such a property.

Proposition C. 8 (Types of expressions are well-formed)

$$
\text { If } \Gamma \vdash e: \beta \text {, then } \Gamma \vdash \beta: * .
$$

By structural induction on the derivation $\Delta$ of $\Gamma \vdash e: \beta$. In this proof we need to consider explicitly all the possible cases for the last rule in $\Delta$; each case is quite simple but needs specific arguments.
(Rules for $\lambda$-terms) If the last rule in $\Delta$ is (Const), we derive the thesis via (Type-Const). To address the (Var) rule we use Lemma C.1.(ii) (Sub-derivation) and Lemma C.2.(i) (Weakening). For the ( $A b s$ ) rule one applies the inductive hypothesis, Lemma C.1.(ii) (Sub-derivation), Lemma C.7.(i) (Substitution), and the (Type-Arrow) rule. About (Appl), the inductive hypothesis allows us to derive $\Gamma \vdash \alpha \rightarrow \beta: *$; this judgment can only be derived through the (Type-Arrow) rule, whose second premise is precisely the thesis.
(Rules for object terms) The thesis is trivial for the (Empty), (Pre-Extend) and (Override) rules. In the (Extend) case, $\Gamma \vdash\left\langle e_{1} \oplus n=e_{2}\right\rangle: \tau \oplus n$ is derived from $\Gamma \vdash \tau \nVdash p r o t .\langle R, n: \sigma\rangle \oplus \bar{m}$; by Proposition C. 4 and Lemma C.3.(i), we have $\Gamma \vdash \operatorname{prot} .\langle R, n: \sigma\rangle \oplus \bar{m}, n: *$; by Lemma C.5.(vii), $\Gamma \vdash \tau \oplus n \nVdash \operatorname{prot} .\langle R, n: \sigma\rangle \oplus \bar{m}, n$, and so we conclude by Proposition C.4. The two remaining cases are more complex.
(Send) We have that $\Gamma \vdash e \Leftarrow n: \sigma[\tau / t]$ is derived from $\Gamma \vdash \tau \nVdash \operatorname{prot} .\langle R, n: \sigma\rangle \oplus \bar{m}, n$, from which, by Proposition C.4, we derive $\Gamma \vdash \operatorname{prot} .\langle R, n: \sigma\rangle \oplus \bar{m}, n: *$ and, in turn, $\Gamma, t \nVdash \operatorname{prot} .\langle R, n: \sigma\rangle \oplus \bar{m}, n \vdash \sigma: *$ by Lemma C.6.(ii); finally, by Proposition C.7.(iii) (Substitution), we can conclude that $\Gamma \vdash \sigma[\tau / t]: *$.
(Select) We have that $\Gamma \vdash \operatorname{Sel}\left(e_{1}, n, e_{2}\right): \sigma[(\tau \oplus \bar{n}) / t]$ is derived from both $\Gamma, t \nVdash$ prot. $\langle R, n: \sigma\rangle \oplus \bar{m}, n \vdash e_{2}: t \rightarrow(t \oplus \bar{n})$ and $\Gamma \vdash \tau \nVdash$ prot. $\langle R, n: \sigma\rangle \oplus \bar{m}, n$. By inductive hypothesis, $\Gamma, t \not \sharp \operatorname{prot} .\langle R, n: \sigma\rangle \oplus \bar{m}, n \vdash t \rightarrow(t \oplus \bar{n}): *$ and, by Proposition C.7.(iii) (Substitution), $\Gamma \vdash \tau \rightarrow(\tau \oplus \bar{n}): *$; then, since this latter judgment can only be obtained via the (Type-Arrow) rule, we deduce $\Gamma \vdash \tau \oplus \bar{n}: *$. Further, we have $\Gamma \vdash \tau \oplus \bar{n} \nVdash$ prot. $\langle R, n: \sigma\rangle \oplus \bar{m}, n$ by case analysis and Lemma C.5.(i)-(iii), from which the thesis by Lemma C.6.(ii) and Proposition C.7.(iii) (Substitution).

Theorem C. 9 (Subject Reduction, $\lambda \mathcal{O b j}{ }^{\oplus}$ ) If $\Gamma \vdash e: \beta$ and $e \rightarrow e^{\prime}$, then $\Gamma \vdash e^{\prime}: \beta$.
We prove that the type is preserved by each of the four reduction rules (Beta), (Selection), (Success) and (Next).
(Beta) The derivation $\Delta$ of $\Gamma \vdash\left(\lambda x . e_{1}\right) e_{2}: \beta$ needs to terminate with a rule (Appl), deriving $\Gamma \vdash\left(\lambda x . e_{1}\right) e_{2}: \alpha$, potentially followed by some applications of (Pre-Extend). Let the premises of (Appl) be $\Gamma \vdash\left(\lambda x . e_{1}\right): \sigma \rightarrow \alpha$ and $\Gamma \vdash e_{2}: \sigma$ for a suitable $\sigma$; in turn, the first judgment has to be derived from $\Gamma, x: \sigma \vdash e_{1}: \alpha$ via the (Abs) rule. By Proposition C.7.(i) (Substitution), we conclude $\Gamma \vdash\left(e_{1}: \alpha\right)\left[e_{2} / x\right] \equiv e_{1}\left[e_{2} / x\right]: \alpha$; then, by repeating the potential applications of (Pre-Extend) in $\Delta$, we have the thesis.
(Selection) The derivation $\Delta$ of $\Gamma \vdash e \Leftarrow n: \beta$ has to terminate with a (Send) rule, deriving $\Gamma \vdash e \Leftarrow n: \sigma[\tau / t]$, potentially followed by applications of (Pre-Extend). The premises of (Send) are $\Gamma \vdash e: \tau$ and $\Gamma \vdash \tau \nVdash \operatorname{prot} .\langle R, n: \sigma\rangle \oplus \bar{m}, n$. From this latter judgment, by Lemma C. 4 (Matching is well-formed) and the rules (Cont-t), (Match-Pro), (Match-Var), (Type-Extend), (Cont-x), (Var), and (Abs), one can derive $\Gamma, t \nVdash \operatorname{prot} .\langle R, n: \sigma\rangle \oplus \bar{m}, n \vdash \lambda s . s: t \rightarrow t$. From the above premises, by applying the (Select) rule, we have $\Gamma \vdash \operatorname{Sel}(e, n, \lambda s . s): \sigma[\tau / t]$ and, by repeating the potential applications of (Pre-Extend) in $\Delta$, the thesis.
(Success) The derivation $\Delta$ of $\Gamma \vdash \operatorname{Sel}\left(\left\langle e_{1} \oplus n=e_{2}\right\rangle, n, e_{3}\right): \beta$ must terminate with a (Select) rule, deriving $\Gamma \vdash S e l\left(\left\langle e_{1} \hookleftarrow n=e_{2}\right\rangle, n, e_{3}\right): \sigma[(\tau \oplus \bar{n}) / t]$, potentially followed by applications of (Pre-Extend). The premises of (Select) are:

$$
\begin{gather*}
\Gamma \vdash\left\langle e_{1} \leftrightarrow n=e_{2}\right\rangle: \tau  \tag{3}\\
\Gamma \vdash \tau \nVdash \text { prot. }\langle R, n: \sigma\rangle \oplus \bar{m}, n  \tag{4}\\
\Gamma, t \nVdash \operatorname{prot} .\langle R, n: \sigma\rangle \oplus \bar{m}, n \vdash e_{3}: t \rightarrow t \oplus \bar{n} \tag{5}
\end{gather*}
$$

From (4) and (5), through the Substitution Lemma, we have $\Gamma \vdash e_{3}: \tau \rightarrow \tau \oplus \bar{n}$; from this latter judgment and (3), by the (Appl) rule, we derive:

$$
\begin{equation*}
\Gamma \vdash e_{3}\left\langle e_{1} \oplus n=e_{2}\right\rangle: \tau \oplus \bar{n} \tag{6}
\end{equation*}
$$

The judgment (3) can only be obtained using either the (Extend) rule or the (Override) one, potentially followed by some applications of (Pre-Extend). Here we consider only the case where (Extend) is applied, since (Override) can be managed similarly, with the difference that in some points the proof is simpler. Hence, let us assume that (Extend) derives $\Gamma \vdash\left\langle e_{1} \oplus n=e_{2}\right\rangle: \rho \oplus n$ from the premise $\Gamma \vdash e_{1}: \rho$ and:

$$
\begin{gather*}
\Gamma \vdash \rho \nVdash \text { prot. }\left\langle R_{1}, n: \sigma_{1}\right\rangle \oplus \bar{p}  \tag{7}\\
\Gamma, t \nVdash p r o t .\left\langle R_{1}, n: \sigma_{1}\right\rangle \oplus \bar{p}, n \vdash e_{2}: t \rightarrow \sigma_{1} \tag{8}
\end{gather*}
$$

By inspection of the (Pre-Extend) rule, we can readily derive $\Gamma \vdash \tau \nVdash \rho \oplus n$. From (7), by Lemma C.5.(vii), we have $\Gamma \vdash \rho \oplus n \not \sharp$ prot. $\left\langle R_{1}, n: \sigma_{1}\right\rangle \oplus \bar{p}, n$, and, by transitivity of matching, $\Gamma \vdash \tau \nVdash$ prot. $\left\langle R_{1}, n: \sigma_{1}\right\rangle \oplus \bar{p}, n$. From this latter judgment and (4), by Lemma C.5.(vi) (Matching uniqueness), it follows that $\sigma \equiv \sigma_{1}$.

On the other hand, by Lemma C.5.(ix), we have $\Gamma \vdash \tau \oplus \bar{n} \not \sharp \tau$ and, by transitivity of matching, $\Gamma \vdash \tau \oplus \bar{n} \not \sharp$ prot. $\left\langle R_{1}, n: \sigma\right\rangle \oplus \bar{p}, n$. From this latter judgment and (8), by the Substitution Lemma, we have $\Gamma \vdash e_{2}: \tau \oplus \bar{n} \rightarrow \sigma[(\tau \oplus \bar{n}) / t]$, and, in turn, from this and (6), $\Gamma \vdash e_{2}\left(e_{3}\left\langle e_{1} \oplus n=e_{2}\right\rangle\right): \sigma[(\tau \oplus \bar{n}) / t]$ via the (Appl) rule. Finally, by repeating the potential applications of (Pre-Extend) in $\Delta$, we obtain the thesis.
(Next) As argued for (Success), the derivation of $\Gamma \vdash \operatorname{Sel}\left(\left\langle e_{1} \oplus n=e_{2}\right\rangle, m, e_{3}\right): \beta$ must end with a (Select) rule, deriving $\Gamma \vdash S e l\left(\left\langle e_{1} \oplus n=e_{2}\right\rangle, m, e_{3}\right): \sigma[(\tau \oplus \bar{m}) / t]$, potentially followed by applications of (Pre-Extend). The premises of (Select) are:

$$
\begin{gather*}
\Gamma \vdash\left\langle e_{1} \oplus n=e_{2}\right\rangle: \tau  \tag{9}\\
\Gamma \vdash \tau \nVdash \operatorname{prot} .\langle R, m: \sigma\rangle \oplus \bar{n}, m  \tag{10}\\
\Gamma, t \nVdash p r o t .\langle R, m: \sigma\rangle \oplus \bar{n}, m \vdash e_{3}: t \rightarrow(t \oplus \bar{m}) \tag{11}
\end{gather*}
$$

The judgment (9) can only be derived using either the (Extend) rule or the (Override) one, potentially followed by some applications of (Pre-Extend). As carried out in
the proof for the (Success) rule, we address here only the case where (Extend) is applied, being the (Override) case similar but simpler.

Since (Pre-Extend) has been applied and (9) holds, $\tau$ must be in the form $\operatorname{prot} .\left\langle R_{1}, m: \sigma, n: \sigma_{1}\right\rangle \oplus \bar{n}, m, n$. Hence, let (9) be derived through (Pre-Extend) from:

$$
\Gamma \vdash\left\langle e_{1} \oplus n=e_{2}\right\rangle: \operatorname{prot} .\left\langle R_{2}, m: \sigma, n: \sigma_{1}\right\rangle \oplus \bar{n}, m, n
$$

(where $R_{2} \subseteq R_{1}$ ), which, in turn, is derived via the (Extend) rule from the premises:

$$
\begin{gather*}
\Gamma \vdash e_{1}: \operatorname{prot} .\left\langle R_{2}, m: \sigma, n: \sigma_{1}\right\rangle \oplus \bar{n}, m  \tag{12}\\
\Gamma \vdash \operatorname{prot} .\left\langle R_{2}, m: \sigma, n: \sigma_{1}\right\rangle \oplus \bar{n}, m \nVdash \operatorname{prot} .\left\langle R_{3}, n: \sigma_{1}\right\rangle \oplus \bar{p}  \tag{13}\\
\Gamma \vdash t \nVdash \operatorname{prot} .\left\langle R_{3}, n: \sigma_{1}\right\rangle \oplus \bar{p}, n \vdash e_{2}: t \rightarrow \sigma_{1} \tag{14}
\end{gather*}
$$

Then, let $\rho$ represent the type prot. $\left\langle R_{1}, m: \sigma, n: \sigma_{1}\right\rangle \oplus \bar{n}, m$, i.e. $\tau \equiv \rho \oplus n$. From the judgment (12), by the (Pre-Extend) rule, we can derive:

$$
\begin{equation*}
\Gamma \vdash e_{1}: \rho \tag{15}
\end{equation*}
$$

By the (Match-Pro) rule, we have $\Gamma \vdash \rho \oplus n \nVdash \operatorname{prot} .\left\langle R_{2}, m: \sigma, n: \sigma_{1}\right\rangle \oplus \bar{n}, m$ and, from this latter judgment, (13) and (14), by transitivity of matching and the Weakening Lemma, we derive $\Gamma, t \not \sharp \rho \oplus n \vdash e_{2}: t \rightarrow \sigma_{1}$. From it, by means of the (Extend) rule:

$$
\begin{equation*}
\Gamma, t \nVdash \rho, s: t \vdash\left\langle s \hookleftarrow n=e_{2}\right\rangle: t \oplus n \tag{16}
\end{equation*}
$$

Now, through (10), the (Match-Var) rule, and the transitivity of matching, one can derive $\Gamma, t \nVdash \rho \vdash t \oplus n \nVdash$ prot. $\langle R, m: \sigma\rangle \oplus \bar{n}, m$. From this latter judgment and (11), by Substitution, we obtain $\Gamma, t \nVdash \rho \vdash e_{3}: t \oplus n \rightarrow t \oplus n \oplus \bar{m}$, and, from this judgment and (16), by the (Appl) and (Abs) rules, we have:

$$
\Gamma, t \nVdash \rho \vdash \lambda s . e_{3}\left\langle s \hookleftarrow n=e_{2}\right\rangle: t \rightarrow t \oplus n \oplus \bar{m}
$$

This judgment, together with (15), allows to apply the (Select) rule, thus deriving:

$$
\Gamma \vdash \operatorname{Sel}\left(e_{1}, m, \lambda s . e_{3}\left\langle s \leftarrow n=e_{2}\right\rangle\right): \sigma[(\rho \oplus n \oplus \bar{m}) / t]
$$

Finally, we get the thesis via the usual potential applications of (Pre-Extend).

## D Soundness of the Type System with Subsumption $\lambda \mathcal{O} b j_{S}^{\oplus}$

Theorem D. 1 (Subject Reduction, $\lambda \mathcal{O} b j_{S}^{\oplus}$ ) If $\Gamma \vdash e: \beta$ and $e \rightarrow e^{\prime}$, then $\Gamma \vdash e^{\prime}: \beta$.
As in Theorem C.9, we prove that the type is preserved by each of the reduction rules (Beta), (Selection), (Success) and (Next). In the present case we have to manage the extra difficulty of potential applications of the (Subsume) rule.
(Beta) The derivation of $\Gamma \vdash\left(\lambda x . e_{1}\right) e_{2}: \beta$ needs to terminate with a rule $(A p p l)$, deriving $\Gamma \vdash\left(\lambda x . e_{1}\right) e_{2}: \alpha$, potentially followed by some applications of (Pre-Extend) and (Subsume). The premises of (Appl) must be $\Gamma \vdash\left(\lambda x . e_{1}\right): \sigma \rightarrow \alpha$ and $\Gamma \vdash e_{2}: \sigma$, where the first judgment has to be derived via ( $A b s$ ), followed by potential applications of (Subsume). Let $\Gamma \vdash\left(\lambda x . e_{1}\right): \sigma_{1} \rightarrow \alpha_{1}$ be the conclusion of the (Abs) rule, and:

$$
\begin{equation*}
\Gamma, x: \sigma_{1} \vdash e_{1}: \alpha_{1} \tag{17}
\end{equation*}
$$

its premise. Since the (Subsume) rule has been applied, we have $\Gamma \vdash \sigma_{1} \rightarrow \alpha_{1} \nVdash \sigma \rightarrow \alpha$ and $\Gamma \vdash \sigma \rightarrow \alpha: *_{r g d}$, therefore $\Gamma \vdash \sigma \nVdash \sigma_{1}$ and $\Gamma \vdash \sigma_{1}: *_{r g d}$ and $\Gamma \vdash \alpha_{1} \nVdash \alpha$, where $\Gamma \vdash \alpha: *_{r g d}$. Using these judgments and (17) it is not difficult to prove, by structural induction, that $\Gamma, x: \sigma \vdash e_{1}: \alpha_{1}$. By Substitution Lemma, we have then $\Gamma \vdash e_{1}\left[e_{2} / x\right]: \alpha_{1}$, and, by the (Subsume) rule, $\Gamma \vdash e_{1}\left[e_{2} / x\right]: \alpha$, from which the thesis.
(Selection) This case works as for the system without subsumption.
(Success) As in Theorem C. 9 (type system without subsumption), we can start by asserting that the derivation $\Delta$ of $\Gamma \vdash \operatorname{Sel}\left(\left\langle e_{1} \oplus n=e_{2}\right\rangle, n, e_{3}\right): \beta$ must end with a (Select) rule, deriving $\Gamma \vdash \operatorname{Sel}\left(\left\langle e_{1} \oplus n=e_{2}\right\rangle, n, e_{3}\right): \sigma[(\tau \oplus \bar{n}) / t]$. This is potentially followed by applications of the (Pre-Extend) rule and, in the present case, also the (Subsume) rule. The premises of (Select) are the following:

$$
\begin{gather*}
\Gamma \vdash\left\langle e_{1} \leftrightarrow n=e_{2}\right\rangle: \tau  \tag{18}\\
\Gamma \vdash \tau \nVdash o b j t .\langle R, n: \sigma\rangle \oplus \bar{m}, n  \tag{19}\\
\Gamma, t \nVdash o b j t .\langle R, n: \sigma\rangle \oplus \bar{m}, n \vdash e_{3}: t \rightarrow t \oplus \bar{n} \tag{20}
\end{gather*}
$$

If the judgment (18) was not obtained by an application of the (Subsume) rule, we could repeat the steps argued to prove Theorem C.9. In fact, we address here the case where (18) is derived by a single application of (Subsume) (it sufficient to consider a single application, because consecutive applications can be always compacted into a single one). Hence, let the premises of (Subsume) be:

$$
\begin{gather*}
\Gamma \vdash\left\langle e_{1} \oplus n=e_{2}\right\rangle: \rho  \tag{21}\\
\Gamma \vdash \rho \nVdash \tau  \tag{22}\\
\Gamma \vdash \tau: *_{r g d} \tag{23}
\end{gather*}
$$

From the judgments (19), (22) and (20), by transitivity of matching and Substitution, we have $\Gamma \vdash e_{2}: \rho \rightarrow \rho \oplus \bar{n}$. From this and (21), by the (Appl) rule, we derive:

$$
\begin{equation*}
\Gamma \vdash e_{3}\left\langle e_{1} \leftarrow n=e_{2}\right\rangle: \rho \oplus \bar{n} \tag{24}
\end{equation*}
$$

Again, by repeating the steps carried out for Theorem C. 9 (case analysis on the derivation of (21)), we can prove that $\Gamma \vdash e_{2}\left(e_{3}\left\langle e_{1} \oplus n=e_{2}\right\rangle\right): \sigma[(\rho \oplus \bar{n}) / t]$.

Now, from (19) and (23) follows that $t$ is covariant in $\sigma$ and $\Gamma \vdash \sigma: *_{r g d}$, and from Lemma 6.12 that $\Gamma \vdash \sigma[(\rho \oplus \bar{n}) / t] \nVdash \sigma[(\tau \oplus \bar{n}) / t]$ and $\Gamma \vdash \sigma[(\tau \oplus \bar{n}) / t]: *_{r g d}$. Finally, by an application of the (Subsume) rule, we have $\Gamma \vdash e_{2}\left(e_{3}\left\langle e_{1} \oplus m=e_{2}\right\rangle\right): \sigma[(\tau \oplus \bar{n}) / t]$, and from this the thesis via the applications of (Pre-Extend) potentially in $\Delta$.
(Next) As in the version without subsumption, we start from the derivation $\Delta$ of $\Gamma \vdash \operatorname{Sel}\left(\left\langle e_{1} \leftrightarrow n=e_{2}\right\rangle, m, e_{3}\right): \beta$, which has to terminate with a (Select) rule, deriving $\Gamma \vdash \operatorname{Sel}\left(\left\langle e_{1} \oplus n=e_{2}\right\rangle, m, e\right): \sigma[(\tau \oplus \bar{m}) / t]$, potentially followed by applications of the (Pre-Extend) and (Subsume) rules. Let the premises of (Select) be:

$$
\begin{gather*}
\Gamma \vdash\left\langle e_{1} \oplus n=e_{2}\right\rangle: \tau  \tag{25}\\
\Gamma \vdash \tau \nVdash \text { obj } t .\langle R, m: \sigma\rangle \oplus \bar{n}, m  \tag{26}\\
\Gamma, t \nVdash \text { objt. }\langle R, m: \sigma\rangle \oplus \bar{n}, m \vdash e_{3}: t \rightarrow(t \oplus \bar{m}) \tag{27}
\end{gather*}
$$

If the judgment (25) was not obtained by an application of the (Subsume) rule, we could repeat the steps argued to prove Theorem C.9. Then, we address here the case where (25) is derived by a single application of (Subsume), from the premises:

$$
\begin{gather*}
\Gamma \vdash\left\langle e_{1} \hookleftarrow n=e_{2}\right\rangle: \rho  \tag{28}\\
\Gamma \vdash \rho \nVdash \tau  \tag{29}\\
\Gamma \vdash \tau: *_{r g d} \tag{30}
\end{gather*}
$$

From these hypotheses, by repeating the same steps argued for the proof without subsumption (case analysis on the derivation of the judgment (28)), we deduce:

$$
\Gamma \vdash \operatorname{Sel}\left(e_{1}, m, \lambda s . e_{3}\left\langle s \hookleftarrow n=e_{2}\right\rangle\right): \sigma[(\rho \oplus n \oplus \bar{m}) / t]
$$

Finally, the proof can be accomplished as in the (Success) case, by applying Lemma 6.12 and by means of the (Subsume) and (Pre-Extend) rules.

[^0]:    ${ }^{1}$ The pro and obj terminology is the same as in Fisher and Mitchell [FM95, FM98].

[^1]:    ${ }^{2}$ An alternative solution would be that reg in alice overrides itself as reg $=\lambda s^{\prime} \cdot \lambda p \cdot\left\langle s^{\prime} \oplus i d=p\right\rangle$; in such an equivalent case only $i d$ methods would be stacked, rather than $\langle i d, e m p\rangle$ pairs.

[^2]:    ${ }^{3}$ Notice that, to ease readability, we will omit from now on the overriden methods, if the latter have definitively become garbage (in the case: the inner versions of emp,id, sal).

[^3]:    ${ }^{4}$ Typing the third method $e m p$ is not problematic, being simpler than in previous Section 7.3 .
