Bounded Backstepping Control and Robustness Analysis for Time-Varying Systems under Converging- Input-Converging-State Conditions *

Frédéric Mazenc Michael Malisoff Laurent Burlion Jerome Weston

August 17, 2017

Abstract

We provide new bounded backstepping results that ensure global asymptotic stability for a large class of partially linear systems with an arbitrarily large number of integrators. We use a dynamic extension that contains one artificial delay, and a converging-input-converging-state assumption. When the nonlinear subsystem is control affine, we provide sufficient conditions for our converging-input-converging-state assumption to hold. We also show input-to-state stability with respect to a large class of model uncertainties, and robustness to delays in the measurements of the state of the nonlinear subsystem. We illustrate our result using an example that is beyond the scope of classical backstepping.

1 Introduction

This paper continues our group's quest (begun in [12], [13], [14], [15], [18], and [19]) for novel backstepping results that help overcome the obstacles to using classical backstepping; see [8] and [10] for traditional backstepping. Classical backstepping entails synthesizing globally asymptotically stabilizing feedback controls, by recursively building globally asymptotically stabilizing controls and corresponding Lyapunov functions for subsystems; see [5], [7], [8], and [11] for improved backstepping theory that can include nonlinearities and uncertainties, and see [2], [3], and [4] for backstepping applied to adaptive, aerospace, and robotic systems. However, there are significant instances that call for backstepping but where the existing backstepping literature does not apply, e.g., systems with general nonlinear subsystems where there are bounds on the allowable sup norms of the controls, which produce challenges that we overcome in this work.

In this work, we focus on systems of the form

$$\begin{cases} \dot{x}(t) &= \mathcal{F}(t, x(t), z(t), \eta(t)) \\ \dot{z}_i(t) &= z_{i+1}(t), \quad i \in \{1, \dots, k-1\} \\ \dot{z}_k(t) &= u(t) + \sum_{j=1}^k v_j z_j(t) \end{cases} \quad (1)$$

with a scalar valued control u and any number $k \geq 2$ of integrators, where x is valued in \mathbb{R}^n for any n , the v_j 's are real constants, the unknown measurable essentially bounded function η represents model uncertainty, and the nonlinear x subsystem will satisfy a converging-input-converging-state condition that we specify below. Many nonlinear systems admit changes of variables that produce the form (1); see the well known results [6, Section 9.1] for formulas for the changes of coordinates, and Section 6 for examples that illustrate

the value of our theory. We write our controls as $u(t)$ to simplify notation, but our controls will be feedbacks that depend on t through their dependence on states of the original system and of a dynamic extension.

In most of what follows, we assume that the current values of the state are available for measurement, but our main result will still use a delay in the state values in our feedback control since this so-called artificial delay is needed to design a bounded control; see Section 5 for an extension to cases where there are also delays in the measurements of the values $x(t)$ of the nonlinear subsystem of (1). Our work [15] also used both the converging-input-converging-state assumption and artificial delays, but a notable improvement in the present work as compared with [15] is that here we allow an arbitrarily large number k of integrators, while [14, 15] only allowed one integrator. Although our bounded backstepping work [18] also allowed an arbitrarily large number of integrators, a notable advantage of the present work over [18] is that we produce a globally bounded control for (1) while the controls for the original systems in [18] were not globally bounded. Also, whereas [18] required k artificial delays in the control and did not use dynamic extensions, here we only require one artificial delay, so in this sense we obtain a simpler feedback.

Our works [12], [13], [14] and [19] did not use converging-input-converging-state conditions or artificial delays. Moreover, our work differs from the backstepping works [13] (which uses a forwarding method to cover the one integrator case), [12] (which also only covers one integrator), [19] (which produces unbounded controls), and [22], [23], and [24] (which use Lie derivatives without satisfying the input constraints that we satisfy here). Therefore, our novel combination of converging-input-converging-state conditions with artificial delays and bounded controllers for (1) is valuable. The work to follow improves on our conference version [16] by also incorporating measurement delays and input-to-state stability with respect to the uncertainties η , and allowing the nonlinear subsystem to depend on all components of the vector z . These three features were not present in [16], which was confined to cases where \mathcal{F} was a function of only (t, x, z_1) and where there were no measurement delays and no input-to-state stability analysis.

We use standard notation and definitions. We omit arguments of functions when they are clear, and the dimensions of our Euclidean spaces are arbitrary unless otherwise noted. We use $|\cdot|$ to denote the usual Euclidean norm and the induced matrix norm, and $|\phi|_\infty$ (resp., $|\phi|_{\mathcal{I}}$) is the essential supremum (resp., supremum over any interval \mathcal{I}) for any bounded measurable function ϕ . We set $\mathbb{N} = \{1, 2, \dots\}$. Given any constant $T > 0$, let C_{in} denote the set of all continuous functions $\phi : [-T, 0] \rightarrow \mathbb{R}^a$, which we call the set of all *initial functions*. We define $\Xi_t \in C_{\text{in}}$ and $\dot{\Xi}_t \in C_{\text{in}}$ by $\Xi_t(s) = \Xi(t+s)$ and $\dot{\Xi}_t(s) = \Xi'(t+s)$ for all choices of Ξ , $s \leq 0$, and $t \geq 0$ for which the equalities are defined. We use the convention $0! = 1$, and assume for simplicity that the initial times for our solutions are $t_0 = 0$ and that the initial functions are constant at time 0 (e.g., the states are constant on $[-T, 0]$, where T will denote the artificial delay). We let $f^{(i)}$ denote the i th derivative of a function $f : [0, +\infty) \rightarrow \mathbb{R}$ with $f^{(0)} = f$, and $\sigma_r : \mathbb{R} \rightarrow [-r, r]$ is the saturation that is defined for all constants $r > 0$ by $\sigma_r(s) = s$ for all $s \in [-r, r]$ and $\sigma_r(s) = r \text{sign}(s)$ otherwise. An integral $\int_a J(\ell) d\ell$ of a continuous column vector valued function $J = (J_1, \dots, J_L)^\top$ on an interval a is defined to be the column vector whose i th entry is $\int_a J_i(\ell) d\ell$ for all i . We use the standard definitions of global asymptotic and input-to-state stability (or ISS, which we also use to mean input-to-state stable) [8].

2 Lemmas and Main Result

We require the following two lemmas, the first of which follows from elementary calculations that we omit:

Lemma 1. *Let $q > 0$ and $T > 0$ be constants, and $\mu_0 : [-T, +\infty) \rightarrow \mathbb{R}$ be any continuous function, and set*

$$\begin{aligned} \zeta(t) &= \int_{t-T}^t e^{q(\ell-t)} Q(t, \ell, \ell+T) \mu_0(\ell) d\ell, \\ \Omega_j(t) &= \zeta^{(j-1)}(t) \text{ and } \mu_i(t) = \frac{1}{T} \int_{t-T}^t e^{q(\ell-t)} \frac{(t-\ell)^{i-1}}{(i-1)!} \mu_0(\ell) d\ell \end{aligned} \quad (2)$$

for all $j \in \{1, \dots, k+1\}$ and $i \in \mathbb{N}$, where $Q(t, a, b) = (t-a)^{k-1} (t-b)^{k-1}$ for all $a \in \mathbb{R}$ and $b \in \mathbb{R}$ and $k \in \mathbb{N}$ with $k \geq 2$. Then there are constants $c_{i,j}(q, T) \in \mathbb{R}$ for all $i \in \{1, \dots, 2k-1\}$ and all $j \in \{1, \dots, k\}$, and constants $g_i(q, T) \in \mathbb{R}$ for all $i \in \{-1, 0, \dots, 2k-1\}$, such that

$$\Omega_j(t) = \sum_{i=1}^{2k-1} c_{i,j}(q, T) \mu_i(t) \text{ and } \Omega_{k+1}(t) = \sum_{i=0}^{2k-1} g_i(q, T) \mu_i(t) + g_{-1}(q, T) \mu_0(t-T) \quad (3)$$

hold for all $t \geq 0$. □

Lemma 1 follows by first using the Binomial Theorem to write $Q(t, \ell, \ell + T)$ as a linear combination of the terms $(t - \ell)^r$ with $k - 1 \leq r \leq 2k - 2$. In the next lemma (which was shown in [21]), we say that a linear system is *not exponentially unstable* provided its poles are all in the closed left-half plane:

Lemma 2. *Let $k \geq 2$ be an integer and $v = (v_1, \dots, v_k)$ be any vector of k real constants such that*

$$\begin{cases} \dot{z}_i(t) &= z_{i+1}(t), \quad i \in \{1, \dots, k-1\} \\ \dot{z}_k(t) &= u + \sum_{i=1}^k v_i z_i \end{cases} \quad (4)$$

is not exponentially unstable when $u = 0$. Then there is a bounded locally Lipschitz function $\vartheta : \mathbb{R}^k \rightarrow \mathbb{R}$ such that (4) in closed loop with $u = \vartheta(Z)$ where $Z = (z_1, \dots, z_k)^\top$ is globally asymptotically and locally exponentially stable to 0. \square

We can now fix functions Λ_j such that the Ω_j 's from Lemma 1 can be written as

$$\Omega_j(t) = \int_{t-T}^t \Lambda_j(\ell, t) \mu_0(\ell) d\ell \quad \text{for } 1 \leq j \leq k \text{ and all } t \geq 0 \quad (5)$$

for all choices of the continuous function $\mu_0 : [-T, +\infty) \rightarrow \mathbb{R}$, where we omit the dependence of the Λ_j 's on q and T for brevity. For instance, we have

$$\begin{aligned} \Lambda_1(\ell, t) &= e^{q(\ell-t)} (t-\ell)^{k-1} (t-\ell-T)^{k-1} \text{ and} \\ \Lambda_2(\ell, t) &= e^{q(\ell-t)} [-q(t-\ell)^{k-1} (t-\ell-T)^{k-1} + (k-1)(t-\ell)^{k-2} (t-\ell-T)^{k-1} \\ &\quad + (k-1)(t-\ell)^{k-1} (t-\ell-T)^{k-2}] \end{aligned} \quad (6)$$

and the formulas for the other Λ_j 's can be computed from Lemma 1. Notice for later use that the Λ_i 's are all bounded on $[t-T, t]$ for each $t \geq 0$ and $T > 0$. For instance, when $k = 2$, we have

$$\max\{|\Lambda_j(\ell, t)| : 1 \leq j \leq 2, \ell \in [t-T, t], t \geq 0\} \leq \max\{T^2, T(qT+2)\} \quad (7)$$

for all $q > 0$. Also, the Λ_i 's can be rewritten as functions of $t - \ell$ and $t - \ell - T$. We will assume the following, where $\Lambda = (\Lambda_1, \dots, \Lambda_k)^\top$:

Assumption 1. (i) *The function \mathcal{F} in (1) is continuous in t and η , globally Lipschitz in (x, z) , and satisfies*

$$\mathcal{F}(t, 0, 0, 0) = 0 \text{ for all } t \geq 0. \quad (8)$$

(ii) *There is a globally Lipschitz bounded function $\omega : \mathbb{R}^n \rightarrow [-\bar{\omega}, \bar{\omega}]$ having some bound $\bar{\omega} > 0$ such that $\omega(0) = 0$ and constants $T > 0$ and $q > 0$ such that for each continuous function $\delta : [0, +\infty) \rightarrow \mathbb{R}^k$ that exponentially converges to 0, the following is true: All solutions $\xi : [0, +\infty) \rightarrow \mathbb{R}^n$ of the system*

$$\dot{\xi}(t) = \mathcal{F}\left(t, \xi(t), \int_{t-T}^t \Lambda(\ell, t) \omega(\xi(\ell)) d\ell + \delta(t), 0\right) \quad (9)$$

satisfy $\lim_{t \rightarrow +\infty} \xi(t) = 0$. \square

We refer to part (ii) of Assumption 1 as our *converging-input-converging-state assumption*; see Section 3 for sufficient conditions for Assumption 1 to hold, and see Section 5 for a generalization involving measurement delays in the ξ measurements in the function ω . The system (9) differs from the nonlinear subsystem of (1) because the third argument of \mathcal{F} in (1) has been replaced by the sum of an integral term and $\delta(t)$, and because η has been set to 0. In terms of the Jordan matrix

$$J_{2k-1} = \begin{bmatrix} -q & 1 & 0 & \dots & 0 \\ 0 & -q & 1 & \dots & 0 \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ \vdots & & \ddots & -q & 1 \\ 0 & \dots & \dots & 0 & -q \end{bmatrix} \in \mathbb{R}^{(2k-1) \times (2k-1)}, \quad (10)$$

our main result is as follows, where the forward completeness of the closed loop system follows from the boundedness of ω and of the control, and the global Lipschitzness properties of \mathcal{F} and ω :

Theorem 1. *Let the constants $q > 0$, $k \geq 2$, and $T > 0$ and the functions \mathcal{F} and ω be such that Assumption 1 holds, where $k \in \mathbb{N}$. Let ϑ and v satisfy the requirements from Lemma 2. Consider the augmented (x, Z, Y) system, consisting of (1) and*

$$\dot{Y}(t) = J_{2k-1}Y(t) + \frac{e_{2k-1}}{T}\omega(x(t)) \quad (11)$$

where $e_{2k-1} = (0, 0, \dots, 1)^\top \in \mathbb{R}^{2k-1}$ is the $(2k-1)$ -st standard basis vector, in closed loop with the control

$$u(Z(t), Y_t, x_t) = \sigma_{\bar{c}}(\mathcal{M}(Y_t)) + g_0(q, T)\omega(x(t)) + g_{-1}(q, T)\omega(x(t-T)) + \vartheta(Z_*(t)) \quad (12)$$

with the saturation level

$$\bar{c} = \left| \sum_{j=1}^k v_j \mathcal{C}_j(q, T) - \mathcal{G}(q, T) \right| e^{|J_{2k-1}|T} \bar{\omega} \quad (13)$$

where $Z_*(t) = (z_1(t) - \mathcal{C}_1(q, T)\Psi(Y_t), \dots, z_k(t) - \mathcal{C}_k(q, T)\Psi(Y_t))^\top$, $\Psi(Y_t) = Y(t) - e^{TJ_{2k-1}}Y(t-T)$, $\mathcal{G}(q, T) = [g_{2k-1}(q, T) \dots g_1(q, T)]$, and

$$\mathcal{M}(Y_t) = \left(\mathcal{G}(q, T) - \sum_{j=1}^k v_j \mathcal{C}_j(q, T) \right) \Psi(Y_t) \quad \text{and} \quad \mathcal{C}_j(q, T) = [c_{2k-1,j}(q, T) \dots c_{1,j}(q, T)], \quad 1 \leq j \leq k \quad (14)$$

and where the constants $c_{i,j}$ and g_i satisfy the requirements from Lemma 1 for the function $\mu_0(t) = \omega(x(t))$. Then all maximal solutions $(x, Z, Y)(t)$ of the augmented (x, Z, Y) system satisfy $\lim_{t \rightarrow +\infty} (x, Z, Y)(t) = 0$ when $\eta = 0$. If, in addition, the system

$$\dot{\xi}(t) = \mathcal{F}\left(t, \xi(t), \int_{t-T}^t \Lambda(\ell, t)\omega(\xi(\ell))d\ell + \delta(t), \eta(t)\right) \quad (15)$$

is ISS with respect to (δ, η) , then the closed loop (x, z) system is ISS with respect to η . \square

Remark 1. *As in [18], we can extend Theorem 1 to cases where in addition to the artificial delay T , there is a delay in the measurements of $x(t)$ from the original system (1). However, as we noted above, [18] does not provide a bounded control for (1) even if the v_i 's are all zero, and the converging-input-converging-state assumption in [18] has a k -fold integral instead of the simpler single integral we have in (9). \square*

We next provide sufficient conditions for our converging-input-converging-state assumption to hold, and then we prove Theorem 1 in Section 4. See also Section 5 for extensions under measurement delays.

3 Checking Assumption 1

We provide sufficient conditions for our converging-input-converging-state conditions on (9) to hold, and for the ISS property of (15) from Theorem 1 to hold, based on Lyapunov functions. We use the system

$$\dot{x}(t) = \mathcal{F}(t, x(t), \Lambda_*(T)\omega(x(t)), \eta(t)), \quad (16)$$

where \mathcal{F} is from (1), $\Lambda_* : [0, \infty) \rightarrow \mathbb{R}^p$ is defined by

$$\Lambda_*(T) = \int_{t-T}^t (\Lambda_1(\ell, t), \dots, \Lambda_p(\ell, t))^\top d\ell, \quad (17)$$

the constant $T > 0$ will be specified, the functions Λ_i 's satisfy the requirements from (5), and $p \in [1, k]$ is such that \mathcal{F} is a function of $(t, x, z_1, \dots, z_p, \eta)$, where z_1, \dots, z_p are the first p components of the state z of the linear subsystem of (1). The definition (17) is justified by the fact that each function $\Lambda_i(\ell, t)$ for $i = 1, 2, \dots, p$ can be written as a function of $t - \ell - T$ and $t - \ell$, so the right side of (17) does not depend on t . We also use the following standard definitions. A function $W : \mathbb{R}^n \rightarrow [0, +\infty)$ is called *positive definite* provided $W(0) = 0$ and $W(x) > 0$ for all $x \in \mathbb{R}^n \setminus \{0\}$. A function $V : [0, +\infty) \times \mathbb{R}^n \rightarrow [0, +\infty)$ is called *uniformly proper and positive definite* provided there are functions $\alpha_0 \in \mathcal{K}_\infty$ and $\alpha_1 \in \mathcal{K}_\infty$ such that the inequalities $\alpha_0(|x|) \leq V(t, x) \leq \alpha_1(|x|)$ hold for all $t \geq 0$ and $x \in \mathbb{R}^n$. This agrees with the *properness* condition in the special case where V is independent of t . Here, \mathcal{K}_∞ is the set of all continuous functions $\gamma : [0, +\infty) \rightarrow [0, +\infty)$ such that $\gamma(0) = 0$, γ is strictly increasing, and $\lim_{s \rightarrow +\infty} \gamma(s) = +\infty$. In the next assumption, V_t and V_x are the partial derivative with respect to t and the gradient with respect to x , respectively, and the uniform global Lipschitzness in x means that the global Lipschitz constants can be chosen independently of the other variable t :

Assumption 2. *There are functions $f : [0, +\infty) \times \mathbb{R}^n \rightarrow \mathbb{R}^n$ and $g : [0, +\infty) \times \mathbb{R}^n \rightarrow \mathbb{R}^{n \times p}$ that are uniformly globally Lipschitz in x and continuous on $[0, +\infty) \times \mathbb{R}^n$, such that $\mathcal{F}(t, x, q, \eta) = f(t, x) + g(t, x)(q + \eta)$ holds for all $t \geq 0$, $x \in \mathbb{R}^n$, $q \in \mathbb{R}^p$, and $\eta \in \mathbb{R}^p$. There exist a C^1 uniformly proper and positive definite function $V : [0, +\infty) \times \mathbb{R}^n \rightarrow [0, +\infty)$; a uniformly continuous positive definite function $W : \mathbb{R}^n \rightarrow [0, +\infty)$; positive constants T , r_0 , r_1 , and r_3 ; and a constant $r_2 \geq 0$ such that for all $(t, x) \in [0, +\infty) \times \mathbb{R}^n$, we have*

$$\begin{aligned} V_t(t, x) + V_x(t, x)(f(t, x) + g(t, x)\Lambda_*(T)\omega(x)) &\leq -W(x), \\ |V_x(t, x)g(t, x)| \leq r_0\sqrt{W(x)}, |\omega(x)| \leq r_1\sqrt{W(x)}, |f(t, x)| \leq r_2\sqrt{W(x)}, \text{ and } |g(t, x)| \leq r_3, \end{aligned} \quad (18)$$

where $\omega : \mathbb{R}^n \rightarrow \mathbb{R}$ is bounded, satisfies $\omega(0) = 0$, and admits a global Lipschitz constant $C > 0$ on \mathbb{R}^n . \square

See [17] for conditions under which (18) can be satisfied. Set

$$\Lambda_a(T) = \int_{t-T}^t |(\Lambda_1, \dots, \Lambda_p)(\ell, t)| d\ell, \quad (19)$$

which is independent of t because the Λ_i 's can be written as functions of $t - \ell$ and $t - \ell - T$. We also set $\Lambda_+(T) = \sup_{t \geq 0} \{ |(\Lambda_1(\ell, t), \dots, \Lambda_p(\ell, t))| : t - T \leq \ell \leq t \}$, which is finite because of our choice of Λ .

Proposition 1. *If Assumption 2 holds, then for all integers $k \geq 2$, and for all constants $T > 0$ such that*

$$4(T\Lambda_a(T)r_0C)^2 \left[2r_2^2 + \frac{5}{2}(r_1r_3T\Lambda_+(T))^2 \right] < 1, \quad (20)$$

Assumption 1 is satisfied. If, in addition, W is proper, then (15) is ISS with respect to (δ, η) . \square

Proof. We first prove the first assertion of the proposition (where $\eta = 0$), and then we indicate the additional arguments needed to prove the second assertion. Fix any continuous function $\delta : [0, +\infty) \rightarrow \mathbb{R}^p$ that exponentially converges to 0. Along all solutions $x(t)$ of (9), the control affine structure of \mathcal{F} gives

$$\dot{x}(t) = f(t, x(t)) + g(t, x(t))\Lambda_*\omega(x(t)) + g(t, x(t)) \left[\delta(t) + \int_{t-T}^t \Lambda^b(\ell, t)(\omega(x(\ell)) - \omega(x(t))) d\ell \right] \quad (21)$$

where $\Lambda^b = (\Lambda_1, \dots, \Lambda_p)^\top$, and therefore also

$$\dot{V}(t) \leq -W(x(t)) + \sqrt{W(x(t))} \left(\left\{ \Lambda_a r_0 \sup_{\ell \in [t-T, t]} |\omega(x(\ell)) - \omega(x(t))| \right\} + r_0 |\delta(t)| \right), \quad (22)$$

where we will omit the argument T of Λ_a and Λ_+ for brevity. We next use the global Lipschitz constant C on ω and apply the Fundamental Theorem of Calculus to find a useful upper bound on the supremum from (22). To this end, we first use Assumption 2 to obtain the upper bound

$$|\dot{x}(t)| \leq r_2\sqrt{W(x(t))} + r_3 \left(|\Lambda_+| \int_{t-T}^t |\omega(x(\ell))| d\ell + |\delta(t)| \right) \quad (23)$$

along all solutions of (9). Applying $(a+b)^2 \leq 2(a^2+b^2)$ and then $(a+b)^2 \leq (5/4)a^2 + 5b^2$ for suitable $a \geq 0$ and $b \geq 0$ and then Jensen's inequality and Assumption 2 that along all solutions of (21), we have

$$\begin{aligned} |\dot{x}(t)|^2 &\leq 2r_2^2W(x(t)) + 2r_3^2 \left(5|\delta(t)|^2 + \frac{5}{4} \left(\int_{t-T}^t \Lambda^b(\ell, t)\omega(x(\ell)) d\ell \right)^2 \right) \\ &\leq 2r_2^2W(x(t)) + 2r_3^2 \left(5|\delta(t)|^2 + \frac{5}{4}T^2r_1^2\Lambda_+^2 \int_{t-T}^t W(x(\ell)) d\ell \right). \end{aligned} \quad (24)$$

We can now combine (22) and (24) and then use Jensen's and Young's inequalities $\sqrt{W(x(t))}b \leq \frac{1}{4}W(x(t)) + b^2$, with $b = r_0|\delta(t)|$ and then b being the quantity in curly braces in (22), to get

$$\begin{aligned} \dot{V}(t) &\leq -\frac{1}{2}W(x(t)) + r_0^2 \left(|\delta(t)|^2 + \Lambda_a^2 C^2 \sup_{\ell \in [t-T, t]} |x(\ell) - x(t)|^2 \right) \\ &\leq -\frac{1}{2}W(x(t)) + r_0^2 \left(|\delta(t)|^2 + \Lambda_a^2 C^2 T \int_{t-T}^t |\dot{x}(\ell)|^2 \right) \\ &\leq -\frac{1}{2}W(x(t)) + r_0^2 \left(|\delta(t)|^2 + \Lambda_a^2 C^2 T \left[2r_2^2 \int_{t-T}^t W(x(\ell)) d\ell + 10r_3^2 T |\delta|_{[t-T, t]}^2 \right. \right. \\ &\quad \left. \left. + \frac{5}{2}r_3^2 T^2 \Lambda_+^2 r_1^2 \int_{t-2T}^t W(x(\ell)) d\ell \right] \right) \\ &\leq -\frac{1}{2}W(x(t)) + \mathcal{N}_1 \int_{t-2T}^t W(x(\ell)) d\ell + \mathcal{N}_2 |\delta|_{[t-T, t]}^2 \end{aligned} \quad (25)$$

along all solutions of (9) for all $t \geq 0$, where

$$\mathcal{N}_1 = T(r_0\Lambda_a C)^2 \left(2r_2^2 + \frac{5}{2}(r_1 r_3 \Lambda_+ T)^2 \right) \quad (26)$$

and $\mathcal{N}_2 = 10(r_0 T \Lambda_a r_3 C)^2 + r_0^2$, by using the bound $\int_{s-T}^s W(x(\ell))d\ell \leq \int_{t-2T}^t W(x(\ell))d\ell$ for all $s \in [t-T, t]$. Then our condition (20) implies that $2T\mathcal{N}_1 < 1/2$, so we can find a constant $\lambda > 1$ that is close enough to 1 so that $2T\mathcal{N}_1\lambda < 1/2$. Then the function

$$V_1(t, x_t) = V(t, x(t)) + \lambda\mathcal{N}_1 \int_{t-2T}^t \int_s^t W(x(\ell))d\ell ds \quad (27)$$

satisfies

$$\dot{V}_1 \leq -\left\{ \frac{1}{2} - 2T\mathcal{N}_1\lambda \right\} W(x(t)) - (\lambda - 1)\mathcal{N}_1 \int_{t-2T}^t W(x(\ell))d\ell + \mathcal{N}_2 |\delta|_{[t-T, t]}^2 \quad (28)$$

for all $t \geq 0$ along all solutions of (9), since

$$\frac{d}{dt} \int_{t-2T}^t \int_s^t W(x(\ell))d\ell ds = 2TW(x(t)) - \int_{t-2T}^t W(x(\ell))d\ell, \quad (29)$$

holds for all $t \geq 0$.

Since the quantity in curly braces in (28) is positive and $\lambda > 1$, and since our assumptions on δ ensure that $|\delta|_{[t-T, t]}^2$ is integrable, we can integrate (28) on $[0, M]$ for any $M > 0$ to get $\sup_{t \geq 0} V_1(t, x_t) < +\infty$. Since V is uniformly proper and positive definite, we conclude that $|x(t)|$ is bounded, so $x(t)$ is uniformly continuous, by the structure of the dynamics (9) when $\eta = 0$. Since W is uniformly continuous, it follows that $W(x(t))$ is a uniformly continuous function of t , and integrating (28) gives

$$\int_0^{+\infty} W(x(\ell))d\ell < +\infty. \quad (30)$$

Therefore, Barbalat's Lemma implies that $\lim_{t \rightarrow +\infty} W(x(t)) = 0$, so since W is positive definite, we conclude that $\lim_{t \rightarrow +\infty} x(t) = 0$. This proves the first assertion of the proposition.

To prove the second assertion of the proposition, fix a choice of the measurable essentially bounded function η . Then the preceding analysis applies to the corresponding system (15), save for the fact that we must add the additional term $V_x(t, x(t))g(t, x(t))\eta(t)$ to the right sides of the decay estimates on V . We can use Jensen's inequality to check that this additional term is bounded above by

$$r_0 \sqrt{W(x(t))} |\eta(t)| \leq \frac{c_*}{2} W(x(t)) + \frac{1}{2c_*} r_0^2 |\eta(t)|^2 \quad (31)$$

where $c_* > 0$ is the constant in curly braces in (28). If we add the right side of (31) to the right side of (28) and use the fact that

$$\int_{t-2T}^t \int_s^t W(x(\ell))d\ell ds \leq 2T \int_{t-2T}^t W(x(\ell))d\ell \quad (32)$$

for all $t \geq 0$, then we can find a function $\gamma_0 \in \mathcal{K}_\infty$ and a constant $k_* > 0$ such that

$$\dot{V}_1 \leq -\gamma_0(V_1(t, x_t)) + k_* |\delta|_{[0, t]}^2 \quad (33)$$

along all solutions of (9), using the properness of V and W to find a $\gamma_1 \in \mathcal{K}_\infty$ such that $\gamma_1(V(t, x)) \leq (c_*/2)W(x)$ for all $t \geq 0$ and $x \in \mathbb{R}^n$, then choosing $\gamma_0(\ell) = \min\{\gamma_1(\ell/2), r_*\ell\}$ with $r_* = (\lambda - 1)/(4T\lambda)$ (by the relation $\gamma_0(a+b) \leq \gamma_0(2a) + \gamma_0(2b)$ where a and b are the terms being added in the formula (27)). Hence, V_1 is an ISS Lyapunov function for the system, so the ISS properties follow by standard arguments [8]. \square

Remark 2. Proposition 2 requires $T > 0$ to be small enough, but due to the structure of our controller in Theorem 1, we cannot pick $T = 0$. In Section 5, we will see how picking T small enough can ensure that the ISS property is maintained even when there are measurement delays D in the x values in our feedbacks. \square

4 Proof of Theorem 1

Theorem 1 will follow from three more lemmas, which we state next. The first of these lemmas follows from [20, Lemma A.3.2] (applied to the entire function $\mathcal{E}(x) = e^{xt}$ for any $t \in \mathbb{R}$ to compute $\mathcal{E}(J_{2k-1})$):

Lemma 3. For the Jordan matrix J_{2k-1} defined in (10), the equality

$$e^{J_{2k-1}t} = e^{-qt} \begin{bmatrix} 1 & t & \frac{t^2}{2} & \cdots & \frac{t^{2(k-1)}}{(2(k-1))!} \\ 0 & 1 & t & \cdots & \frac{t^{2k-3}}{(2k-3)!} \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ \vdots & & & 1 & t \\ 0 & \cdots & \cdots & 0 & 1 \end{bmatrix} \quad (34)$$

holds for all $t \in \mathbb{R}$ and integers $k \geq 2$. \square

Later in the proof of Theorem 1, we specialize the following lemma to the case where $\mu_0(t) = \omega(x(t))$:

Lemma 4. Let $\mu_0 : [-T, +\infty) \rightarrow [-\bar{\mu}, \bar{\mu}]$ be any continuous function having a bound $\bar{\mu}$. Then the functions μ_i from (2) in Lemma 1, and the functions $\Psi(Y_t) = Y(t) - e^{TJ_{2k-1}}Y(t-T)$ for all solutions Y of

$$\dot{Y}(t) = J_{2k-1}Y(t) + \frac{e^{2k-1}}{T}\mu_0(t), \quad (35)$$

are such that for all $t \geq 0$, we have

$$\nu_{2k-1}(t) = \Psi(Y_t) \quad \text{and} \quad |\Psi(Y_t)| \leq e^{|J_{2k-1}|T}\bar{\mu}, \quad (36)$$

where $\nu_{2k-1}(t) = (\mu_{2k-1}(t), \dots, \mu_1(t))^\top$ for all $t \geq 0$. \square

Proof. By integrating (35), we deduce that

$$\Psi(Y_t) = Y(t) - e^{TJ_{2k-1}}Y(t-T) = \varrho(t), \quad \text{where} \quad \varrho(t) = \int_{t-T}^t e^{J_{2k-1}(t-\ell)} \frac{e^{2k-1}}{T} \mu_0(\ell) d\ell \quad (37)$$

for all $t \geq 0$. On the other hand, using (34), we obtain

$$\varrho(t) = \frac{1}{T} \int_{t-T}^t e^{-q(t-\ell)} \begin{bmatrix} \frac{(t-\ell)^{2(k-1)}}{(2(k-1))!} \\ \vdots \\ t-\ell \\ 1 \end{bmatrix} \mu_0(\ell) d\ell = \nu_{2k-1}(t), \quad (38)$$

which proves the first conclusion of the lemma. The second conclusion of the lemma follows since (37) gives the estimate

$$|Y(t) - e^{TJ_{2k-1}}Y(t-T)| \leq \int_{t-T}^t |e^{J_{2k-1}(t-\ell)} \frac{e^{2k-1}}{T}| \bar{\mu} d\ell \quad (39)$$

for all $t \geq 0$, which proves the lemma. \square

Lemma 5. Let $\mu_0 : [-T, +\infty) \rightarrow [-\bar{\mu}, \bar{\mu}]$ be any continuous function having a bound $\bar{\mu}$, and let the constants v_i and the function ϑ satisfy the requirements from Lemma 2. Consider the linear system

$$\begin{cases} \dot{z}_i(t) &= z_{i+1}(t), \quad i \in \{1, \dots, k-1\} \\ \dot{z}_k(t) &= u(t) + \sum_{j=1}^k v_j z_j(t) \end{cases} \quad (40)$$

in closed loop with the control

$$u(Z(t), Y_t, x_t) = \sigma_{\bar{c}}(\mathcal{M}(Y_t)) + g_0(q, T)\mu_0(t) + g_{-1}(q, T)\mu_0(t-T) + \vartheta(Z_*(t)) \quad (41)$$

with the saturation level \bar{c} for $\sigma_{\bar{c}}$ defined by

$$\bar{c} = \left| \sum_{j=1}^k v_j \mathcal{C}_j(q, T) - \mathcal{G}(q, T) \right| e^{|J_{2k-1}|T} \bar{\mu} \quad (42)$$

and where Y satisfies (35) and \mathcal{M} , Z_* , \mathcal{G} , and the \mathcal{C}_j 's and g_j 's are defined as in Theorem 1. Then the dynamics for the vector $\tilde{Z}(t) = (\tilde{z}_1(t), \dots, \tilde{z}_k(t))$ are globally asymptotically and locally exponentially stable to the origin, where $\tilde{z}_i(t) = z_i(t) - \Omega_i(t)$ for $i = 1, 2, \dots, k$ and the Ω_i 's are defined in (2) in Lemma 1. \square

Proof. The fact that $\dot{\Omega}_i = \Omega_{i+1}$ for all $i \in \{1, 2, \dots, k\}$ and the structure of the dynamics (40) allow us to conclude that the dynamics for the functions $\tilde{z}_i(t) = z_i(t) - \Omega_i(t)$ are

$$\begin{cases} \dot{\tilde{z}}_i(t) &= \tilde{z}_{i+1}(t), \quad i \in \{1, \dots, k-1\} \\ \dot{\tilde{z}}_k(t) &= u(t) - \Omega_{k+1}(t) + \sum_{j=1}^k v_j [\tilde{z}_j(t) + \Omega_j(t)] \end{cases} \quad (43)$$

Using our conclusion from Lemma 4 that

$$\nu_{2k-1}(t) = \Psi(Y_t) \quad (44)$$

where $\nu_{2k-1}(t) = (\mu_{2k-1}(t), \dots, \mu_1(t))^\top$ as before, it follows from (3) that

$$\begin{aligned} \dot{\tilde{z}}_i(t) &= u(t) - \mathcal{G}(q, T)\nu_{2k-1}(t) - g_0(q, T)\mu_0(t) - g_{-1}(q, T)\mu_0(t-T) \\ &\quad + \sum_{j=1}^k v_j \tilde{z}_j(t) + \sum_{j=1}^k v_j \mathcal{C}_j(q, T)\nu_{2k-1}. \end{aligned} \quad (45)$$

Hence, (44) gives

$$\begin{cases} \dot{\tilde{z}}_i(t) &= \tilde{z}_{i+1}(t), \quad i \in \{1, \dots, k-1\} \\ \dot{\tilde{z}}_k(t) &= u(t) + \sum_{j=1}^k v_j \tilde{z}_j(t) - g_0(q, T)\mu_0(t) - g_{-1}(q, T)\mu_0(t-T) + \bar{g}\Psi(Y_t) \end{cases} \quad (46)$$

where

$$\bar{g} = \sum_{j=1}^k v_j \mathcal{C}_j(q, T) - \mathcal{G}(q, T). \quad (47)$$

Next note that since Lemma 1 gives $\Omega_j = \mathcal{C}_j(q, T)\nu_{2k-1}$ for $j = 1, \dots, k$, it follows that

$$\tilde{z}_i(t) = z_i(t) - \Omega_i(t) = z_i(t) - \mathcal{C}_i(q, T)\nu_{2k-1}(t) \text{ for } i \in \{1, \dots, k\}. \quad (48)$$

Thus, (44) gives $\tilde{z}_i(t) = z_i(t) - \mathcal{C}_i(q, T)\Psi(Y_t)$ for all $t \geq 0$ and all $i \in \{1, \dots, k\}$, so $Z_*(t) = \tilde{Z}(t)$ for all $t \geq 0$. Also, $\mathcal{M}(Y_t) = -\bar{g}\Psi(Y_t)$. Therefore, our choice (41) of the control gives

$$\begin{cases} \dot{\tilde{z}}_i(t) &= \tilde{z}_{i+1}(t), \quad i \in \{1, \dots, k-1\} \\ \dot{\tilde{z}}_k(t) &= \sum_{j=1}^k v_j \tilde{z}_j(t) + \sigma_{\bar{c}}(-\bar{g}\Psi(Y_t)) + \bar{g}\Psi(Y_t) + \vartheta(Z_*(t)). \end{cases} \quad (49)$$

According to (36), we have

$$|\bar{g}\Psi(Y_t)| \leq |\bar{g}| e^{|J_{2k-1}|T} \bar{\mu} = \bar{c} \quad (50)$$

for all $t \geq 0$. From the definition of the saturation level \bar{c} of $\sigma_{\bar{c}}$, it follows that for all $t \geq 0$, we have

$$\begin{cases} \dot{\tilde{z}}_i(t) &= \tilde{z}_{i+1}(t), \quad i \in \{1, \dots, k-1\} \\ \dot{\tilde{z}}_k(t) &= \vartheta(\tilde{Z}(t)) + \sum_{i=1}^k v_i \tilde{z}_i(t) \end{cases} \quad (51)$$

so the lemma follows from our choice of ϑ in Lemma 2. \square

We now combine the preceding lemmas to prove Theorem 1. We begin by proving the first conclusion of the theorem, in which $\eta = 0$. In this case, the closed loop system is

$$\begin{cases} \dot{x}(t) &= \mathcal{F}(t, x(t), z(t), 0) \\ \dot{z}_i(t) &= z_{i+1}(t), \quad i \in \{1, \dots, k-1\} \\ \dot{z}_k(t) &= u(Z(t), Y_t, x_t) + \sum_{j=1}^k v_j z_j(t) \\ \dot{Y}(t) &= J_{2k-1}Y(t) + \frac{e^{2k-1}}{T}\omega(x(t)). \end{cases} \quad (52)$$

Using the preceding lemma with $\mu_0(t) = \omega(x(t))$, we deduce that

$$\lim_{t \rightarrow +\infty} |z_i(t) - \Omega_i(t)| = 0 \quad (53)$$

for all $i = 1$ to k , and $\tilde{z}_i = z_i - \Omega_i$ exponentially converges to 0 for all i .

Next notice that the x subsystem of (52) can be written as

$$\dot{x}(t) = \mathcal{F}(t, x(t), \Omega(t) + \tilde{z}(t), 0) \quad (54)$$

when we choose the bounded function $\mu_0(t) = \omega(x(t))$. Hence, we can use Assumption 1 to conclude that $\lim_{t \rightarrow +\infty} |x(t)| = 0$ and therefore that for all $i \in \{1, 2, \dots, k\}$, we have $\lim_{t \rightarrow +\infty} \Omega_i(t) = 0$, since $\omega(0) = 0$ and ω is continuous at 0. It follows that

$$\lim_{t \rightarrow +\infty} z(t) = \lim_{t \rightarrow +\infty} (z(t) - \Omega(t)) + \lim_{t \rightarrow +\infty} \Omega(t) = 0. \quad (55)$$

Since $\dot{Y} = J_{2k-1}Y + \varepsilon$ is ISS with respect to ε , this proves the first conclusion of Theorem 1.

It remains to prove the second conclusion of the theorem. To this end, first note that with the notation from our proof of the first conclusion of the theorem, the dynamics for \tilde{z} are globally asymptotically stable to 0, so the interconnection of the perturbed dynamics $\dot{x}(t) = \mathcal{F}(t, x(t), \Omega(t) + \tilde{z}(t), \eta(t))$ with $\mu'_0(t) = \omega(x(t))$ and the \tilde{z} dynamics will be ISS with respect to η , by standard small gain arguments. Then the structure of the function Ω implies that the $(x, z) = (x, \tilde{z} + \Omega)$ dynamics are ISS with respect to η . This completes the proof of our theorem.

5 Extension to Systems with Measurement Delays

Although [18] did not provide a bounded backstepping controller for the original system (1), it allowed cases where current values of the x components of the state of the original system were not available for use in the control, leading to feedback controls in which $x(t)$ must be replaced by time delayed values $x(t - D)$ of x for a constant delay $D > 0$. In the same way, we can extend Theorem 1 above to allow cases where one must use time lagged values of x instead of current ones. This is done by replacing $\omega(x(\ell))$ in the preceding analysis by $\omega(x(\ell - D))$ for constant values of the delay D , so instead of placing a converging-input-converging-state assumption on (9) in Assumption 1, we must replace (9) by the delayed version

$$\dot{\xi}(t) = \mathcal{F}\left(t, \xi(t), \int_{t-T}^t \Lambda(\ell, t) \omega(\xi(\ell - D)) d\ell + \delta(t), 0\right), \quad (56)$$

and then the conclusions of the theorem remain true with $x(\ell)$ replaced by $x(\ell - D)$ in the feedback control. However, our sufficient conditions from Proposition 1 do not apply in cases such as (56) with measurement delays. This motivates the following analog of Proposition 1 that provides sufficient conditions for our delayed version of the converging-input-converging-state condition to hold, and which can therefore facilitate checking the requirements of our theorem when constant measurement delays D are introduced in the x measurements. In what follows, we use the same choices of $\Lambda_a(T)$ from (19) and $\Lambda_+(T) = \sup_{t \geq 0} \{|\Lambda_1(\ell, t), \dots, \Lambda_p(\ell, t)| : t - T \leq \ell \leq t\}$ as in Section 3, which are still independent of t , and which also do not depend on D .

Proposition 2. *If Assumption 2 holds, and if the constants $T > 0$ and $D > 0$ are such that*

$$\begin{aligned} \mathcal{R}(T) < 1 \text{ and } r_0 C \Lambda_a(T) (r_2 + r_3 \Lambda_+(T) r_1 (D + T)) (D + T) < \frac{1 - \mathcal{R}(T)}{8\sqrt{2}}, \text{ where} \\ \mathcal{R}(T) = 4(T \Lambda_a(T) r_0 C)^2 \left[2r_2^2 + \frac{5}{2} (r_1 r_3 T \Lambda_+(T))^2 \right] \end{aligned} \quad (57)$$

then the following is true: For each continuous function $\delta : [0, +\infty) \rightarrow \mathbb{R}^p$ that exponentially converges to zero, all solutions of (56) converge to 0 as $t \rightarrow +\infty$. If, in addition, the function W from Assumption 2 is proper, then the system

$$\dot{\xi}(t) = \mathcal{F}\left(t, \xi(t), \int_{t-T}^t \Lambda(\ell, t) \omega(\xi(\ell - D)) d\ell + \delta(t), \eta(t)\right) \quad (58)$$

is ISS with respect to (δ, η) .

Proof. We indicate the changes needed in the proof of Proposition 1. We let $c_* > 0$ be the constant in curly braces in (28) as before, and where λ is chosen as in the proof of Proposition 1. We may assume that $\lambda > 1$ is close enough to 1 so that the requirements from (57) are still true if we replace $\mathcal{R}(T)$ by $\mathcal{R}(T) = 4\lambda(T\Lambda_a(T)r_0C)^2[2r_2^2 + 2.5(r_1r_3T\Lambda_+(T))^2]$ (by the strictness of the inequalities in (57)), and we make this replacement in the rest of the proof. Then, using our notation from the proof of Proposition 1, we have $c_* = 0.5(1 - \mathcal{R}(T)) = 0.5(1 - 4T\mathcal{N}_1\lambda)$. In what follows, we use Λ_a and Λ_+ to mean $\Lambda_a(T)$ and $\Lambda_+(T)$, respectively, to keep our notation simple. Using the function V from Assumption 2 and Young's Inequality, the additional term that must be added to the decay estimate on V can be bounded above as follows:

$$\begin{aligned}
& V_x(t, x(t))g(t, x) \int_{t-T}^t \Lambda^b(\ell, t) [\omega(x(\ell - D)) - \omega(x(\ell))] d\ell \leq Cr_0\Lambda_a \sqrt{W(x(t))} \int_{t-T-D}^t |\dot{x}(s)| ds \\
& \leq Cr_0\Lambda_a \sqrt{W(x(t))} \int_{t-T-D}^t \left\{ |f(s, x(s))| + |g(s, x(s))| \left[\Lambda_+ \int_{s-T}^s |\omega(x(\ell - D))| d\ell + |\eta(s)| \right] \right\} ds \\
& \leq Cr_0\Lambda_a \sqrt{W(x(t))} \int_{t-T-D}^t \left(r_2 \sqrt{W(x(s))} + r_3\Lambda_+ \int_{t-D-2T}^t |\omega(x(\ell - D))| d\ell + r_3|\eta(s)| \right) ds \\
& \leq Cr_0\Lambda_a \sqrt{W(x(t))} \left[(r_2 + r_3\Lambda_+r_1(D+T)) \int_{t-2D-2T}^t \sqrt{W(x(\ell))} d\ell + r_3(D+T)|\eta|_{[0,t]} \right] \\
& \leq \frac{c_*}{4} W(x(t)) + \frac{1}{c_*} \left(r_0C\Lambda_a \left[(r_2 + r_3\Lambda_+r_1(D+T)) \int_{t-2(D+T)}^t \sqrt{W(x(\ell))} d\ell + r_3(D+T)|\eta|_{[0,t]} \right] \right)^2 \\
& \leq \frac{c_*}{4} W(x(t)) + \frac{4}{c_*} \{r_0C\Lambda_a (r_2 + r_3\Lambda_+r_1(D+T))\}^2 (D+T) \int_{t-2D-2T}^t W(x(\ell)) d\ell \\
& \quad + \frac{2}{c_*} (Cr_0r_3\Lambda_a(D+T))^2 |\eta|_{[0,t]}^2,
\end{aligned}$$

where the last inequality also used Young's inequality, the relation $(a+b)^2 \leq 2a^2 + 2b^2$ for suitable nonnegative values of a and b , and then Jensen's inequality. Using the second inequality in (57) and choosing $\lambda > 1$ close enough to 1, it follows that we can find a constant $\lambda_* > 1$ that is close enough to 1 and which is such that

$$\frac{8\lambda_*}{c_*} \{r_0C\Lambda_a(D+T) (r_2 + r_3\Lambda_+r_1(D+T))\}^2 < \frac{c_*}{4}, \quad (59)$$

since $c_* = 0.5(1 - \mathcal{R}(T))$. Then reasoning analogously to the argument that produced (28) shows that the time derivative of

$$\begin{aligned}
V_2(t, x_t) &= \\
V_1(t, x_t) &+ \frac{4\lambda_*}{c_*} \{r_0C\Lambda_a (r_2 + r_3\Lambda_+r_1(D+T))\}^2 (D+T) \int_{t-2(D+T)}^t \int_{\ell}^t W(x(s)) ds d\ell
\end{aligned} \quad (60)$$

along all solutions of (58) admits positive constants c_{**} and c_{***} such that $\dot{V}_2 \leq -c_{**}W(x(t)) + c_{***}|\delta, \eta|_{[0,t]}^2$. If, in addition, W is proper, then we can argue as in the proof of Proposition 1 to find a function $\gamma_a \in \mathcal{K}_\infty$ and a positive constant k_a such that

$$\dot{V}_2 \leq -\gamma_a(V_2(t, x_t)) + k_a|\delta, \eta|_{[0,t]}^2 \quad (61)$$

(by using the bound (32) except with T in (32) replaced by $D+T$). Then the rest of the proof is the same as in the last part of the proof of Proposition 1 except with V_1 replaced by V_2 . \square

6 Illustrations

Our Lyapunov function based sufficient conditions are convenient for checking our assumptions from Theorem 1. We illustrate this point in this section, in two examples. In our first example, we apply our Lyapunov sufficient conditions directly. In our second example, our Lyapunov sufficient conditions do not apply directly, but we use a mixture of our Lyapunov and trajectory based methods to check our converging-input-converging-state conditions. For simplicity, this section only considers cases where there are no measurement delays D , but we can apply the methods from the preceding section to cover measurement delays as well.

6.1 First Illustration

Consider the three-dimensional system

$$\begin{cases} \dot{x}(t) &= \frac{|x(t)|}{1+|x(t)|} + z_1(t) \\ \dot{z}_1(t) &= z_2(t) \\ \dot{z}_2(t) &= u(t) \end{cases} \quad (62)$$

which is not amenable to classical backstepping, because the right side of $\dot{x}(t)$ in the dynamics is not differentiable. In terms of our notation from Section 3, we choose $k = 2$, $n = 1$, $q = 1$, $p = 1$, and

$$\mathcal{F}(t, x, z_1) = \frac{|x|}{1+|x|} + z_1 \quad \text{and} \quad \omega(x) = -\frac{1}{\Lambda_*(T)} \left(\frac{|x|}{1+|x|} + 2\frac{x}{1+|x|} \right), \quad (63)$$

where

$$\Lambda_*(T) = \int_{-T}^0 \Lambda_1(\ell + t, t) d\ell = \int_{-T}^0 e^{q\ell} \ell^{k-1} (\ell + T)^{k-1} d\ell = 2 - T - e^{-T}(2 + T). \quad (64)$$

We compute a constant $T > 0$ such that Assumption 1 is satisfied. First note that since $p = 1$, and since Λ_1 is nonpositive valued, we have $\Lambda_a(T) = -\Lambda_*(T) = |\Lambda_*(T)|$. Since (63) are globally Lipschitz functions and \mathcal{F} is an affine function of z_1 and ω is bounded, it suffices to find constants r_i for $i = 0, 1, 2, 3$ and functions V and W such that Assumption 2 is satisfied with

$$f(t, x) = \frac{|x|}{1+|x|} \quad \text{and} \quad g(t, x) = 1 \quad (65)$$

and then to choose T such that our condition (20) holds.

To this end, we check that Assumption 2 is satisfied using the functions

$$V(t, x) = \int_0^x \sigma_1(\ell) d\ell \quad \text{and} \quad W(x) = \frac{2\sigma_1(x)x}{1+|x|}. \quad (66)$$

Since (65) give

$$f(t, x) + g(t, x)\Lambda_*(T)\omega(x) = -\frac{2x}{1+|x|} \quad (67)$$

our conditions (18) on the r_i 's from Assumption 2 for the preceding choices of f , g , V , and W will be satisfied if

$$|\sigma_1(x)| \leq r_0 \sqrt{\frac{2\sigma_1(x)x}{1+|x|}}, \quad \frac{1}{|\Lambda_*(T)|} \frac{3|x|}{1+|x|} \leq r_1 \sqrt{\frac{2\sigma_1(x)x}{1+|x|}}, \quad \frac{|x|}{1+|x|} \leq r_2 \sqrt{\frac{2\sigma_1(x)x}{1+|x|}}, \quad \text{and} \quad 1 \leq r_3. \quad (68)$$

By separately considering points $x \in [-1, 1]$ and points $x \notin [-1, 1]$, it follows easily that Assumption 2 is satisfied with the choices

$$C = \frac{3}{|\Lambda_*(T)|}, \quad r_0 = 1, \quad r_1 = \frac{3}{\sqrt{2}|\Lambda_*(T)|}, \quad r_2 = 1, \quad \text{and} \quad r_3 = 1. \quad (69)$$

Hence, our requirement (20) on $T > 0$ from Proposition 1 holds if

$$1 > 4(3T)^2 \left[2 + \frac{5}{2} \left(\frac{3T^3}{\sqrt{2}|2-T-e^{-T}(2+T)|} \right)^2 \right] \quad (70)$$

and we can use Mathematica [25] to check that the right side of (70) takes the value 0.912536 at $T = 0.11$. Hence, Assumption 1 is satisfied with $T = 0.11$, and then the desired controller is provided by Theorem 1.

6.2 Second Illustration

We can sometimes apply Theorem 1 by checking Assumption 1 through a mixture of Lyapunov and direct trajectory analyses. For instance, consider the three dimensional system

$$\begin{cases} \dot{x} &= x^2 - x^3 + z_1 \\ \dot{z}_1 &= z_2 \\ \dot{z}_2 &= u. \end{cases} \quad (71)$$

As noted in [8, pages 593-594], the system (71) is globally asymptotically stabilized to 0 by the control

$$u(x, z) = -\frac{\partial V_0}{\partial z_1}(x, z_1) + \frac{\partial \phi}{\partial z_1}(x, z_1)z_2 - z_2 + \frac{\partial \phi}{\partial x}(x, z_1)(x^2 - x^3 + z_1) + \phi(x, z_1),$$

where $V_0(x, z_1) = \frac{1}{2}x^2 + \frac{1}{2}(z_1 + x + x^2)^2$ and $\phi(x, z_1) = -2x - (1 + 2x)(x^2 - x^3 + z_1) - z_1 - x^2$,

which is unbounded since it satisfies $\lim_{x \rightarrow \infty} u(x, 0) = -\infty$. Our work [18] provided the unbounded control

$$u(t) = \frac{q^2}{(1-e^{-q\tau})^2} \{ J(x(t)) - 2e^{-q\tau} J(x(t-\tau)) + e^{-2q\tau} J(x(t-2\tau)) \} - 2qz_2(t) - q^2z_1(t), \quad (72)$$

where $J(x) = -\sin\left(\frac{\pi x}{2}\right) \mathbf{1}_{[-2,2]}(x)$

that rendered (71) globally asymptotically stable to 0, where the indicator function $\mathbf{1}_{[-2,2]}$ is defined to be 1 on $[-2, 2]$, and 0 on $\mathbb{R} \setminus [-2, 2]$. Here we show how our new Theorem 1 provides a globally bounded globally asymptotically stabilizing controller for (71), using the choice of $\omega = J/\Lambda_*(T)$ with J as defined in (72), and with $q = 1$, $p = 1$, and $k = 2$ and with the artificial $T > 0$ to be specified.

To verify Assumption 1 with the preceding choices, first note that for each continuous function $\delta : \mathbb{R} \rightarrow \mathbb{R}$ that exponentially converges to 0 and each initial state $x_0 \in \mathbb{R}$, we can find a value $T_*(x_0, \delta) \in [0, \infty)$ such that the corresponding solution of

$$\dot{x}(t) = x^2(t) - x^3(t) + \int_{t-T}^t \Lambda_1(\ell, t)\omega(x(\ell))d\ell + \delta(t) \quad (73)$$

satisfies $x(t) \in [-0.8, 3/2]$ for all $t \geq T_*(x_0, \delta)$. This can be done by noting that the integral in (73) is bounded by 1, that $x^2 - x^3 \leq -1.125$ for all $x \geq 3/2$, and that $x^2 - x^3 \geq 1.152$ for all $x \leq -0.8$, so the right side terms $x^2(t) - x^3(t)$ in (73) dominate the other right side terms, since we may assume that t is large enough so that $|\delta(t)| \leq 0.12$. Hence, it suffices to check the inequalities (18) from Assumption 2 for all $x \in [-0.8, 3/2]$, by only considering time values $t \geq T_*(x_0, \delta)$.

We now check the estimates from (18) for all $x \in [-0.8, 3/2]$ using $V(x) = \frac{1}{2}x^2$, $W(x) = x^2$, $f(x) = x^2 - x^3$, and $g(x) = 1$. First note that simple calculations (e.g., using Mathematica [25]) give $x^2 - x^3 - \sin(\pi x/2) \leq -x$ (resp., $\geq -x$) for all $x \in [0, 3/2]$ (resp., $x \in [-0.8, 0]$) which gives $\nabla V(x)(f(x) + \omega(x)) \leq -W(x)$, $|x^2 - x^3| \leq 1.44|x|$, and $|\sin(\pi x/2)| \leq (\pi/2)|x|$ when $x \in [-0.8, 3/2]$, so we can choose $r_0 = 1$, $r_1 = \pi/(2|\Lambda_*(T)|)$, $r_2 = 1.44$, $r_3 = 1$, and $C = \pi/(2|\Lambda_*(T)|)$. Hence, we can use our formula (64) for $\Lambda_*(T)$ and Mathematica to check that the sufficient condition (20) from Proposition 1 (for $\lim_{t \rightarrow \infty} x(t) = 0$ to hold) is satisfied if

$$1 > (T\pi)^2 \left(2(1.44)^2 + \frac{5\pi^2}{8} \left(\frac{T^3}{2 - T - e^{-T}(2 + T)} \right)^2 \right) \quad (74)$$

which is satisfied for all $T \in (0, 0.0209]$. Therefore, we can satisfy our requirements with $T = 0.0209$, and then the desired bounded control is provided by Theorem 1.

7 Conclusions

We provided a new bounded backstepping technique for a large class of cascaded partially linear systems with arbitrarily large numbers of integrators, under a converging-input-converging-state assumption involving the nonlinear subsystems. For many cases where the nonlinear part of the system is control affine, we used Lyapunov functions to provide sufficient conditions for our converging-input-converging-state assumption to be satisfied. Although our controller involves a dynamic extension, it has an advantage that it provides bounded controllers for the original system, which would not have been possible under our assumptions if we had instead relied on previous results. We plan to combine our new methods with the time delay methods in [1] and [9] to also allow arbitrarily long measurement delays.
