---

## Abstract

A new technique is proposed to construct observers and to achieve output feedback stabilization of a class of continuous-time switched linear systems with a time-varying delay in the output. The delay is a piecewise continuous bounded function of time and no constraint is imposed on the delay derivative. For stability analysis, an extension of a recent trajectory based approach is used; this is fundamentally different from classical Lyapunov function based methods. A stability condition is given in terms of the upper bound on the time-varying delay to ensure global uniform exponential stability of the switched feedback system. The main result applies in cases where some of the subsystems of the switched system are not stabilizable and not detectable.

*Key words:* Switched systems, delay, output feedback, observer, stabilization.

---

## 1 Introduction

Switched systems have extensive applications in networks, automotive control, power systems, aircraft and air traffic control, process control, mechanical systems, and many other domains; see Lin and Antsaklis (2009), and the references therein. Due to this strong motivation, many questions related to switched systems such as stability (Liberzon (2003); Liberzon and Morse (1999); Sun and Ge (2011)), controllability (Liu *et al.* (2013); Sun *et al.* (2002)), observability and reachability (Hespanha *et al.* (2005); Ji *et al.* (2007); Sun *et al.* (2002); Tanwani *et al.* (2013)), and synthesis (Pettersson (2003); Sun and Ge (2005)), have been extensively studied in various contributions. Stability and stabilization are challenging problems pertaining to switched systems due to their hybrid nature and they are the main topic of the present paper.

There are mainly two approaches used in the literature for establishing the stability of switched systems:

(i) It is shown in Liberzon and Morse (1999) that existence of a common strict Lyapunov function is a necessary and sufficient condition for the switched system to be stable under arbitrary switching. On the other hand, when such a Lyapunov function exists, finding it may be a difficult task because it is an NP-hard problem; see Blondel and Tsitsiklis (1997). (ii) Liberzon and Morse (1999) also showed that even if a switched system does not possess a common strict Lyapunov function, it may be stable under a dwell-time requirement, typically derived using multiple strict Lyapunov functions. It is worth mentioning that multiple Lyapunov functions may lead to an undesirable attenuation property which can only be mitigated by imposing some strong assumptions; see Zhai *et al.* (2001).

Both of the above mentioned approaches are mainly developed for non-delayed systems. But measurement delays are present in many practical applications, such as chemical processes, aerodynamics and communication networks, and they are time-varying (see for instance Wu and Grigoriadis (2001); Yan and Özbay (2005)). Therefore, the problem of stabilizing switched systems when a time-varying delay is present in the output is strongly motivated. State feedback stabilization of delayed switched linear systems is proposed in Vu and Morgansen (2010) using a combi-

nation of the multiple Lyapunov functions approach and the merging switching signal technique. An online and offline state feedback controller design for delayed switched linear systems in the detection of the switching signal are discussed in Xie and Wang (2005). Moreover, Koru *et al.* (2018) and Yan *et al.* (2014) present state feedback designs for delayed switched systems using a dwell-time based stability analysis approach. Note that Koru *et al.* (2018), Vu and Morgansen (2010), Xie and Wang (2005), and Yan *et al.* (2014) assume that all of the subsystems of the switched system are controllable. Finally, a state feedback stabilization problem for a class of delayed switched systems is studied in Kim *et al.* (2006) and Sun *et al.* (2008) under the assumption that the subsystems satisfy a certain Hurwitz convex combination condition. A common Lyapunov function approach is used in Kim *et al.* (2006) and Sun *et al.* (2008) to carry out stability analysis.

*Contributions of this study:* We propose a new technique to design observers and stabilizing dynamic output feedbacks offering robust stability results with respect to the presence of a time-varying pointwise delay in the output of the switched linear system. To establish the stability of the closed-loop switched system, we develop an extension of the trajectory based stability result recently proposed in Mazenc and Malisoff (2015), and Mazenc, Malisoff, and Niculescu (2017). We wish to point out that the new extension of the trajectory based approach we state and prove in the present paper is of interest by itself: it can be applied to a wide range of systems, notably to families of systems with time-varying delays wider than those invoked in Mazenc and Malisoff (2015), and Mazenc, Malisoff, and Niculescu (2017), and therefore it is one of the important contributions of our work.

We think that our main result can be regarded as an extension of Kim *et al.* (2006), Koru *et al.* (2018), Sun *et al.* (2008), Vu and Morgansen (2010), Xie and Wang (2005), Yan *et al.* (2014), and Zhai *et al.* (2000), offering new advantages because, (i) our study does not assume that all the states are available for feedback, (ii) it is not limited to systems whose all subsystems are stabilizable and detectable, (iii) we use a new extension of trajectory based approach for stability analysis which circumvents the serious obstacle presented by the search for appropriate Lyapunov functions, (iv) the application of our results is not restricted to the class of delayed switched systems where all the convex combinations of the subsystems in the absence of control must be Hurwitz, (v) we allow the delay to be time-varying and piecewise continuous function of time, and we do not impose any constraint on the upper bound of the delay derivative.

Now, we point out that the present paper is a continuation of our conference paper Mazenc *et al.* (2017). We propose a significant extension of it by including, (i) dynamic output feedback stabilization, (ii) a new extension of trajectory based approach of Mazenc and Malisoff (2015) to produce less conservative results, (iii) a sys-

tematic way to compute an explicit value for the lower bound on the largest admissible delay for a broad family of switched systems so that when the delay is smaller than this bound, global uniform exponential stability (GUES) of the feedback switched systems is guaranteed. Moreover, we do not assume that the systems have synchronous switching sequences.

*Organization of the paper:* An extension of the trajectory based approach is given in Section 2. Section 3 is devoted to the main result of the paper. Section 4 discusses computational issues related to the delay bound. The results are illustrated by a numerical example in Section 5. Finally, we summarize and highlight our contributions in Section 6.

*Notation:* The notation will be simplified whenever no confusion can arise from the context.  $I$  denotes the identity matrix of any dimension. The usual Euclidean norm of vectors, and the induced norm of matrices, are denoted by  $|\cdot|$ . Given any constant  $\tau > 0$ , we let  $C([-\tau, 0], \mathbb{R}^n)$  denote the set of all continuous  $\mathbb{R}^n$ -valued functions that are defined on  $[-\tau, 0]$ . We abbreviate this set as  $C_{\text{in}}$ , and call it the set of all *initial functions*. Also, for any continuous function  $x : [-\tau, \infty) \rightarrow \mathbb{R}^n$  and all  $t \geq 0$ , we define  $x_t$  by  $x_t(\theta) = x(t + \theta)$  for all  $\theta \in [-\tau, 0]$ , i. e.,  $x_t \in C_{\text{in}}$  is the translation operator. A vector or a matrix is nonnegative (resp. positive) if all of its entries are nonnegative (resp. positive). We write  $M \succ 0$  (resp.  $M \preceq 0$ ) to indicate that  $M$  is a symmetric positive definite (resp. negative semi-definite) matrix. For two vectors  $V = (v_1 \dots v_n)^\top$  and  $U = (u_1 \dots u_n)^\top$ , we write  $V \leq U$  to indicate that for all  $i \in \{1, \dots, n\}$ ,  $v_i \leq u_i$ .

## 2 Extension of the trajectory based approach

We now provide with an extension of the trajectory based approach given in Mazenc and Malisoff (2015).

**Lemma 1** *Let us consider a constant  $T > 0$  and  $l$  functions  $z_g : [-T, +\infty) \rightarrow [0, +\infty)$ ,  $g = 1, \dots, l$ . Let  $Z(t) = (z_1(t) \dots z_l(t))^\top$  and, for any  $\theta \geq 0$  and  $t \geq \theta$ ,*

*define  $\mathfrak{V}_\theta(t) = \left( \sup_{s \in [t-\theta, t]} z_1(s) \dots \sup_{s \in [t-\theta, t]} z_l(s) \right)^\top$ . Let*

*$\Upsilon \in \mathbb{R}^{l \times l}$  be a nonnegative Schur stable matrix. If for all  $t \geq 0$ , the inequalities  $Z(t) \leq \Upsilon \mathfrak{V}_T(t)$  are satisfied, then  $\lim_{t \rightarrow +\infty} z_g(t) = 0 \quad \forall g = 1, \dots, l$ .*

**Proof.** Since  $\Upsilon$  is Schur stable, there is an integer  $q > 1$  such that

$$|\Upsilon^q| \sqrt{l} < 1. \quad (1)$$

From Lemma 4 of the Appendix A, we deduce that

$$Z(t) \leq \Upsilon^q \mathfrak{V}_{qT}(t) \quad (2)$$

for all  $t \geq qT$ . Consequently,  $|Z(t)| \leq |\Upsilon^q| |\mathfrak{V}_{qT}(t)|$ .

Using  $|\mathfrak{B}_{qT}(t)| \leq \sqrt{l} \sup_{s \in [t-qT, t]} |Z(s)|$ , we obtain

$$|Z(t)| \leq |\Upsilon^q| \sqrt{l} \sup_{s \in [t-qT, t]} |Z(s)|.$$

This inequality, in combination with the inequality (1) and (Mazenc and Malisoff, 2015, Lemma 1), allows us to conclude the result.  $\square$

### 3 Observer and control design

We introduce a range dwell-time condition, i.e. a sequence of real numbers  $t_k$  such that there are two positive constants  $\underline{\delta}$  and  $\bar{\delta}$  such that  $t_0 = 0$  and for all  $k \in \mathbb{Z}_{\geq 0}$ ,

$$t_{k+1} - t_k \in [\underline{\delta}, \bar{\delta}]. \quad (3)$$

**Definition 1** Let  $\pi = \{(i_0, t_0), \dots, (i_k, t_k), \dots, |i_k \in \Xi, k \in \mathbb{Z}_{\geq 0}\}$  be a switching sequence. The function  $\sigma : [0, \infty) \rightarrow \Xi = \{1, \dots, n\}$  such that  $\sigma(t) = i_k$  when  $t \in [t_k, t_{k+1})$  is called an associated *switching signal*.

We consider the continuous-time switched linear system:

$$\begin{cases} \dot{x}(t) = A_{\sigma(t)}x(t) + B_{\sigma(t)}u(t) \\ y(t) = C_{\sigma(t)}x(t - \tau(t)) \end{cases} \quad (4)$$

with  $x \in \mathbb{R}^{d_x}$ ,  $u \in \mathbb{R}^{d_u}$ ,  $y \in \mathbb{R}^{d_y}$ , for all  $t \geq 0$ ,  $\tau(t) \in [0, \bar{\tau}]$  with  $\bar{\tau} > 0$  and an initial condition in  $C_{\text{in}}$ . The delay  $\tau(t)$  is supposed to be a piecewise continuous function. For any  $i \in \Xi$ ,  $A_i$ ,  $B_i$ , and  $C_i$  are real and constant matrices of compatible dimensions and  $\sigma$  is a switching signal. We introduce an assumption which pertains to the stabilizability and the detectability of the system (4), but does not imply that all the pairs  $(A_i, B_i)$  are stabilizable and all the pairs  $(A_i, C_i)$  are detectable.

**Assumption 1** *There are matrices  $K_i$  and  $L_i$  for all  $i \in \Xi$  and constants  $T \geq \bar{\tau}$ ,  $a \in [0, 1)$ ,  $b \geq 0$ ,  $c \in [0, 1)$  and  $d \geq 0$  such that the solutions of the system*

$$\dot{\alpha}(t) = M_{\sigma(t)}\alpha(t) + \zeta(t) \quad (5)$$

with  $M_i = A_i + B_i K_i$  and  $\zeta$  being a piecewise continuous function, satisfy

$$|\alpha(t)| \leq a|\alpha(t - T)| + b \sup_{\ell \in [t-T, t]} |\zeta(\ell)| \quad (6)$$

for all  $t \geq T$ . Similarly, the solutions of the system

$$\dot{\beta}(t) = N_{\sigma(t)}\beta(t) + \eta(t) \quad (7)$$

with  $N_i = A_i + L_i C_i$  and  $\eta$  being a piecewise continuous function, satisfy the following inequality for all  $t \geq T$

$$|\beta(t)| \leq c|\beta(t - T)| + d \sup_{\ell \in [t-T, t]} |\eta(\ell)|. \quad (8)$$

**Theorem 1** *Let the system (4) satisfy Assumption 1 and,  $s_1$ ,  $s_2$  and  $s_3$  be defined by*

$$s_1 = \sup_{i \in \Xi} |B_i K_i|, \quad s_2 = \sup_{i \in \Xi} |L_i C_i|, \quad s_3 = \sup_{i \in \Xi} |M_i|. \quad (9)$$

If

$$\tau(t) \leq \bar{\tau} < \bar{\tau}_u \quad (10)$$

for all  $t \geq 0$ , where

$$\bar{\tau}_u = \frac{(1-a)(1-c)}{ds_1 s_2 ((1-a) + bs_3)}, \quad (11)$$

then the origin of the following feedback system is GUES:

$$\begin{cases} \dot{x}(t) = A_{\sigma(t)}x(t) + B_{\sigma(t)}K_{\sigma(t)}\hat{x}(t) \\ \dot{\hat{x}}(t) = A_{\sigma(t)}\hat{x}(t) + B_{\sigma(t)}K_{\sigma(t)}\hat{x}(t) \\ \quad + L_{\sigma(t)}[C_{\sigma(t)}\hat{x}(t) - y(t)]. \end{cases} \quad (12)$$

**Proof.** Let us introduce  $\tilde{x}(t) = \hat{x}(t) - x(t)$ . Then,

$$\dot{\tilde{x}}(t) = A_{\sigma(t)}\tilde{x}(t) + L_{\sigma(t)}[C_{\sigma(t)}\hat{x}(t) - C_{\sigma(t)}x(t - \tau(t))].$$

As an immediate consequence, using the definitions of the matrices  $M_i$  and  $N_i$ , we obtain

$$\begin{cases} \dot{x}(t) = M_{\sigma(t)}x(t) + B_{\sigma(t)}K_{\sigma(t)}\tilde{x}(t) \\ \dot{\tilde{x}}(t) = N_{\sigma(t)}\tilde{x}(t) + L_{\sigma(t)}C_{\sigma(t)}[x(t) - x(t - \tau(t))]. \end{cases}$$

From Assumption 1 and the equality  $x(t) - x(t - \tau(t)) = \int_{t-\tau(t)}^t [M_{\sigma(m)}x(m) + B_{\sigma(m)}K_{\sigma(m)}\tilde{x}(m)] dm$ , it follows that, for all  $t \geq T + \bar{\tau}$ ,

$$|x(t)| \leq a|x(t - T)| + b \sup_{\ell \in [t-T, t]} |B_{\sigma(\ell)}K_{\sigma(\ell)}\tilde{x}(\ell)|, \quad (13)$$

$$\begin{aligned} |\tilde{x}(t)| &\leq c|\tilde{x}(t - T)| + d \sup_{\ell \in [t-T, t]} |L_{\sigma(\ell)}C_{\sigma(\ell)} \\ &\times \int_{\ell-\tau(\ell)}^{\ell} [M_{\sigma(m)}x(m) + B_{\sigma(m)}K_{\sigma(m)}\tilde{x}(m)] dm \Big|. \end{aligned} \quad (14)$$

Using the constants defined in (9), we deduce from (13) and (14) that  $(x(t), \tilde{x}(t))$  satisfies:

$$\begin{aligned} |x(t)| &\leq a|x(t - T)| + bs_1 \sup_{\ell \in [t-T-\bar{\tau}, t]} |\tilde{x}(\ell)|, \\ |\tilde{x}(t)| &\leq ds_2 s_3 \bar{\tau} \sup_{\ell \in [t-T-\bar{\tau}, t]} |x(\ell)| \\ &\quad + (c + ds_1 s_2 \bar{\tau}) \sup_{\ell \in [t-T-\bar{\tau}, t]} |\tilde{x}(\ell)|. \end{aligned}$$

Lemma 1 ensures that the origin of (12) is GUES if

$$\begin{bmatrix} a & bs_1 \\ ds_2s_3\bar{\tau} & ds_1s_2\bar{\tau} + c \end{bmatrix}$$

is Schur stable, which is equivalent to

$$\frac{a+c+ds_1s_2\bar{\tau}}{2} + \sqrt{\left(\frac{a+c+ds_1s_2\bar{\tau}}{2}\right)^2 - ac - ds_1s_2(a - bs_3)\bar{\tau}} < 1,$$

from which we derive the simpler condition (10).  $\square$

#### 4 Parameters of the delay bound

In this section, we illustrate a method to determine the constants  $a, b, c$ , and  $d$  appearing in Assumption 1. Consider a continuous-time switched linear system

$$\dot{\xi}(t) = \Omega_{\sigma(t)}\xi(t) + \vartheta(t), \quad (15)$$

where  $\xi \in \mathbb{R}^{d_\xi}$ , the switching signal  $\sigma$  is associated to a sequence  $t_k$  of the type of those introduced in Section 3 and  $\vartheta$  is a piecewise continuous function.

**Lemma 2** *Let the system (15) be such that there are real numbers  $d_1 > 0, d_2 > 0, \mu \geq 1, \gamma > 0$  and symmetric positive definite matrices  $Q_l, l \in \Xi$ , such that the LMIs*

$$d_1I \preceq Q_i \preceq d_2I, \quad (16)$$

$$Q_i \preceq \mu Q_j, \quad (17)$$

$$\Omega_i^\top Q_i + Q_i \Omega_i \preceq -\gamma Q_i \quad (18)$$

are satisfied for all  $i, j \in \Xi$ . Moreover, the constant  $\mu_\Delta = \mu e^{-\gamma \underline{\delta}}$  is such that

$$\mu_\Delta < 1. \quad (19)$$

Then, along the trajectory of (15), the inequality

$$|\xi(t)| \leq \sqrt{\frac{d_2}{d_1} \mu \mu_\Delta^\rho e^{\gamma \bar{\delta}}} |\xi(t-T)| + \sqrt{\mu \frac{d_2}{\gamma d_1} T} \sup_{\ell \in [t-T, t]} |\vartheta(\ell)|$$

holds for all  $t \geq T$  where  $T > 0$  and  $\rho$  is a positive integer depending on the choice of  $T$  such that for all  $t \in [t_k, t_{k+1})$ , we have  $t - T \in [t_{k-\rho-1}, t_{k-\rho})$ . Moreover, we have  $\sqrt{\frac{d_2}{d_1} \mu \mu_\Delta^\rho e^{\gamma \bar{\delta}}} < 1$  when  $\rho > \frac{1}{\ln(\mu_\Delta)} \left[ \ln \left( \frac{d_1}{d_2 \mu} \right) - \gamma \bar{\delta} \right]$ .

For the proof of Lemma 2, see Appendix B.

#### Remark 1

1. Note that (19) holds if and only if  $\underline{\delta} > \frac{\ln(\mu)}{\gamma}$ , which defines a minimum dwell-time condition.

2. Conditions of Lemma 2 are always satisfied when the matrices  $\Omega_i, \forall i \in \Xi$ , are Hurwitz; i.e., one can always find symmetric positive definite matrices  $Q_i, i \in \Xi$ , and real numbers  $d_1 > 0, d_2 > 0, \mu \geq 1, \gamma > 0$  satisfying the LMIs (16), (17) and (18). In the next section we illustrate an alternative approach for the case where some of  $\Omega_i$ 's are not Hurwitz.

#### 5 Illustrative Example

Consider the continuous-time switched linear system (4) with  $x \in \mathbb{R}^2, \tau \in [0, \bar{\tau})$ ,

$$\sigma(t) = \begin{cases} 1 & \text{if } 4\ell\kappa \leq t < (4\ell + 3)\kappa \\ 2 & \text{if } (4\ell + 3)\kappa \leq t < 4(\ell + 1)\kappa, \end{cases} \quad (20)$$

where  $\kappa > 0$  is to be determined,  $\ell = 0, 1, 2, \dots$ , and

$$A_1 = \begin{bmatrix} 0 & -1/2 \\ 2/5 & 0 \end{bmatrix}, B_1 = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, C_1 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix},$$

$$A_2 = \begin{bmatrix} 0 & -2/5 \\ 1/2 & 0 \end{bmatrix}, B_2 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, C_2 = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}.$$

Let us observe that the subsystem  $(A_1, B_1, C_1)$  is not stabilizable but it is detectable whereas the subsystem  $(A_2, B_2, C_2)$  is stabilizable but not detectable. Moreover, in the absence of control, no convex combination of the  $A_1$  and  $A_2$  is Hurwitz. Furthermore, the subsystems cannot be stabilized by a static output feedback  $u = K_i y$ . In this example, we have  $\underline{\delta} = \kappa$  and  $\bar{\delta} = 3\kappa$  and the switchings are periodic with a period of  $4\kappa$ . We will determine a set of parameters for the delay bound depending on  $\kappa$ .

##### 5.1 Preliminary result

First, we provide a preliminary result which shows how Assumption 1 can be satisfied in this particular example where some of the subsystems of the switched systems are not stabilizable and not detectable.

**Lemma 3** *Consider the switched linear system*

$$\dot{z}(t) = \Gamma_{\sigma(t)} z(t) + \varrho(t) \quad (21)$$

with  $\sigma$  defined by (20), and let  $\Gamma_1 \in \mathbb{R}^{2 \times 2}, \Gamma_2 \in \mathbb{R}^{2 \times 2}$  and  $\kappa > 0$  be such that the matrix  $S_\kappa := e^{\Gamma_2 \kappa} e^{3\Gamma_1 \kappa}$  is Schur stable. Let  $\Phi_\star$  be the state transition matrix of the system (21) with  $\varrho = 0$ :

$$\frac{\partial \Phi_\star}{\partial t}(t, s) = \Gamma_{\sigma(t)} \Phi_\star(t, s), \quad \Phi_\star(s, s) = I,$$

for all  $t \in \mathbb{R}$  and  $s \in \mathbb{R}$ . Then, for all  $s \geq 0, t \geq s$

$$|\Phi_\star(t, s)| \leq p_1 e^{-p_2(t-s)} \quad (22)$$

with  $p_1 = e^{8\kappa \max\{|\Gamma_1|, |\Gamma_2|\}} c_\kappa e^{2d_\kappa}$  and  $p_2 = d_\kappa/4\kappa$ , where  $c_\kappa > 1$  and  $d_\kappa > 0$  are such that for all  $m \in \mathbb{N}$ ,

$$|S_\kappa^m| \leq c_\kappa e^{-d_\kappa m}. \quad (23)$$

Moreover, for all  $T > 0$ ,

$$|z(t)| \leq p_1 e^{-p_2 T} |z(t-T)| + \frac{p_1(1-e^{-p_2 T})}{p_2} \sup_{\ell \in [t-T, t]} |q(\ell)|. \quad (24)$$

For the proof of Lemma 3, see Appendix C.

**Remark 2** Since  $p_2 > 0$ , then  $p_1 e^{-p_2 T} < 1$  when  $T > \frac{\ln(p_1)}{p_2}$ , which determines a lower bound for  $T$ .

### 5.2 Output feedback stabilization

Let us choose the gain matrices as

$$K_2 = \begin{bmatrix} -1/2 & 0 \\ 0 & -4/7 \end{bmatrix}, \quad L_1 = \begin{bmatrix} -3/5 & 0 \\ 0 & -4/5 \end{bmatrix}.$$

Setting  $\Gamma_1 = M_1 = A_1$  and  $\Gamma_2 = M_2 = A_2 + B_2 K_2$ , one can easily corroborate that (23) is satisfied with the choice of  $\kappa = 0.1$ ,  $c_\kappa = 1.01$ , and  $d_\kappa = 0.001$  for all  $m \in \mathbb{N}$ . Setting  $z = \alpha$ ,  $\Omega_i = \Gamma_i = M_i$  for  $i \in \{1, 2\}$ , and  $\varrho = \zeta$ , it can be easily verified that (22) is satisfied by (5) with  $p_1 = e^{8\kappa \max\{|\Gamma_1|, |\Gamma_2|\}} c_\kappa e^{2d_\kappa} = 1.7142$  and  $p_2 = d_\kappa/4\kappa = 1.0025$ . Using Lemma 3 with  $T = 6$ , one can observe that the solutions of system (5) satisfy (6) with  $a = p_1 e^{-p_2 T} = 0.0042$ ,  $b = (p_1/p_2)(1 - e^{-p_2 T}) = 1.7057$ . A similar analysis shows that the solutions of system (7) satisfy (8) with  $c = 0.0052$ ,  $d = 2.1156$  and  $T = 6$ . Therefore, we conclude that the switched delay system satisfies Assumption 1. Finally, application of Theorem 1 with  $s_1 = 0.5714$ ,  $s_2 = 0.8$ ,  $s_3 = 0.7611$ , and with the preceding choices of the parameters yields  $\bar{\tau}_u = 0.4465$ . Fig. 1 shows the simulation of system (12) for this particular example for a piecewise continuous sawtooth function  $\tau(t)$  of a fundamental frequency of 1 Hz described by  $\tau(t) = 0.2(t - \lfloor t \rfloor)$  where the switching signal  $\sigma(t)$  is given by (20) with  $\kappa = 0.1$ . The initial conditions are chosen to be  $x_1(0) = -0.5$ ,  $x_2(0) = -1$ ,  $\hat{x}_1(0) = 0.5$ , and  $\hat{x}_2(0) = 1$ , and the sample rate is 1 kHz.

It is worth emphasizing here that Vu and Morgansen (2010) assumes that all of the modes of the delayed switched system are controllable and Sun *et al.* (2008) requires the derivative of the delay to be bounded which makes it impossible to apply their results to this example; and it also seems to us that there is no direct way to extend them to the output feedback case considered in this paper.

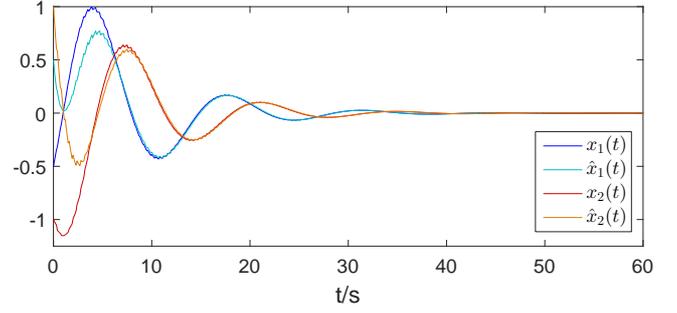

Fig. 1. Simulation results.

## 6 Conclusions

We presented dynamic output feedback stabilization results for systems with switches in the difficult case where a time-varying pointwise delay in the output is present. The technique of proof we proposed is based on the recent trajectory based approach. To solve the conservatism problem we encountered in Mazenc *et al.* (2017), we developed an extension of the main result of Mazenc and Malisoff (2015), which is of interest for its own sake. Many extensions of the results of the present paper are possible, pertaining for instance to design of  $K_i$  and  $L_i$  for maximization of the delay bound, robustness issues with respect to disturbances, the presence of a delay in the input, the design of reduced order observers and extensions to families of nonlinear systems.

### A Technical lemma

**Lemma 4** Let  $R \in \mathbb{R}^{m \times m}$  be a nonnegative matrix. Let us consider functions  $w_j : [0, +\infty) \rightarrow [0, +\infty)$ ,  $j = 1, \dots, m$ , and a constant  $h > 0$  such that for all  $t \geq h$ ,  $w = (w_1 \dots w_m)^\top$  satisfies

$$w(t) \leq R\zeta(t) \quad (A.1)$$

$$\text{with } \zeta(t) = \begin{pmatrix} \sup_{\ell \in [t-h, t]} w_1(\ell) & \dots & \sup_{\ell \in [t-h, t]} w_m(\ell) \end{pmatrix}^\top.$$

Then, for all integer  $k$  larger than 1, and all  $t \geq kh$ , we have  $w(t) \leq R^k \Psi_k(t)$

$$\text{with } \Psi_k(t) = \begin{pmatrix} \sup_{\ell \in [t-kh, t]} w_1(\ell) & \dots & \sup_{\ell \in [t-kh, t]} w_m(\ell) \end{pmatrix}^\top.$$

**Proof.** We prove the lemma by induction:

*Induction Assumption:* There is  $l \in \mathbb{N}$ ,  $l > 0$  such that the result of Lemma 4 holds for all  $k \in \{1, \dots, l\}$ .

*Step 1:* The assumption is satisfied at the step 1.

*Step l:* Let us assume that it is satisfied at the step  $l \geq 1$ . Then the inequalities

$$w(t) \leq R^l \Psi_l(t) \quad (A.2)$$

hold for all  $t \geq lh$ . From (A.1), we deduce that for all  $t \geq (l+1)h$  and  $\ell \in [t-lh, t]$ , the inequalities

$$\begin{pmatrix} w_1(\ell) \\ \vdots \\ w_m(\ell) \end{pmatrix} \leq R \begin{pmatrix} \sup_{s \in [\ell-h, \ell]} w_1(s) \\ \vdots \\ \sup_{s \in [\ell-h, \ell]} w_m(s) \end{pmatrix} \leq R \Psi_{l+1}(t)$$

hold. It follows that

$$\Psi_l(t) \leq R \Psi_{l+1}(t). \quad (\text{A.3})$$

By combining (A.2) and (A.3), we deduce that

$$w(t) \leq R^{l+1} \Psi_{l+1}(t)$$

for all  $t \geq (l+1)h$ . Thus the induction assumption is satisfied at the step  $l+1$ . This concludes the proof.  $\square$

## B Proof of Lemma 2

Let us define Lyapunov functions:

$$\mathcal{V}_i(\xi) = \xi^\top Q_i \xi, \quad \forall i \in \Xi.$$

We deduce from (18) that when  $\sigma(t) = i$ , then the derivative of  $\mathcal{V}_i$  along the trajectories of (15) satisfies

$$\begin{aligned} \dot{\mathcal{V}}_i(\xi(t)) &\leq -2\gamma \mathcal{V}_i(\xi(t)) + 2\xi(t)^\top Q_i \vartheta(t) \\ &\leq -\gamma \mathcal{V}_i(\xi(t)) + \frac{1}{\gamma} \vartheta(t)^\top Q_i \vartheta(t) \end{aligned} \quad (\text{B.1})$$

where the last inequality is deduced from the Young's inequality. Now, let us integrate (B.1) between two instants  $s$  and  $t$ ,  $t \geq s$ , belonging to the same sampling interval where  $\sigma(t) = l$ . Then

$$\begin{aligned} \mathcal{V}_l(\xi(t)) &\leq e^{\gamma(s-t)} \mathcal{V}_l(\xi(s)) \\ &\quad + \frac{1}{\gamma} \int_s^t e^{\gamma m - \gamma t} \vartheta(m)^\top Q_l \vartheta(m) dm \\ &\leq e^{\gamma(s-t)} \mathcal{V}_l(\xi(s)) + \frac{d_2}{\gamma} \int_s^t e^{\gamma m - \gamma t} |\vartheta(m)|^2 dm, \end{aligned} \quad (\text{B.2})$$

where the last inequality is a consequence of (16). Now, let us consider  $T > 0$ ,  $t \geq T$  such that  $t \in [t_k, t_{k+1})$  for some  $k \in \mathbb{Z}_{\geq 0}$  and let  $\rho \in \mathbb{N}$  be such that  $t - T \in [t_{k-\rho-1}, t_{k-\rho})$ . From (B.2), we deduce that

$$\begin{aligned} \mathcal{V}_{\sigma(t_k)}(\xi(t)) &\leq e^{-\gamma(t-t_k)} \mathcal{V}_{\sigma(t_k)}(\xi(t_k)) \\ &\quad + \frac{d_2}{\gamma} \int_{t_k}^t e^{\gamma m - \gamma t} |\vartheta(m)|^2 dm \\ &\leq \mu e^{-\gamma(t-t_k)} \mathcal{V}_{\sigma(t_{k-1})}(\xi(t_k)) + \frac{d_2}{\gamma} \int_{t_k}^t |\vartheta(m)|^2 dm, \end{aligned} \quad (\text{B.3})$$

where the last inequality is a consequence of (17). For similar reasons,

$$\begin{aligned} \mathcal{V}_{\sigma(t_{k-1})}(\xi(t_k)) &\leq \mu \Delta \mathcal{V}_{\sigma(t_{k-2})}(\xi(t_{k-1})) \\ &\quad + \frac{d_2}{\gamma} \int_{t_{k-1}}^{t_k} |\vartheta(m)|^2 dm \\ &\quad \vdots \end{aligned} \quad (\text{B.4})$$

$$\begin{aligned} \mathcal{V}_{\sigma(t_{k-\rho})}(\xi(t_{k-\rho+1})) &\leq \mu \Delta \mathcal{V}_{\sigma(t_{k-\rho-1})}(\xi(t_{k-\rho})) \\ &\quad + \frac{d_2}{\gamma} \int_{t_{k-\rho}}^{t_{k-\rho+1}} |\vartheta(m)|^2 dm \end{aligned}$$

$$\begin{aligned} \mathcal{V}_{\sigma(t_{k-\rho-1})}(\xi(t_{k-\rho})) &\leq e^{\gamma(t-T-t_{k-\rho})} \mathcal{V}_{\sigma(t_{k-\rho-1})}(\xi(t-T)) \\ &\quad + \frac{d_2}{\gamma} \int_{t-T}^{t_{k-\rho}} |\vartheta(m)|^2 dm. \end{aligned} \quad (\text{B.5})$$

Combining (B.3), (B.4) and (B.5), and then using the definition of range dwell-time condition from (3), we get

$$\begin{aligned} \mathcal{V}_{\sigma(t_k)}(\xi(t)) &\leq \mu \mu_\Delta^\rho e^{\gamma \bar{\delta}} \mathcal{V}_{\sigma(t_{k-\rho-1})}(\xi(t-T)) \\ &\quad + \mu \frac{d_2}{\gamma} \int_{t-T}^t |\vartheta(m)|^2 dm. \end{aligned}$$

Using (16) and the inequality  $\sqrt{p_1 + p_2} \leq \sqrt{p_1} + \sqrt{p_2}$  for all  $p_1 \geq 0$ ,  $p_2 \geq 0$ , we obtain

$$|\xi(t)| \leq \sqrt{\frac{d_2}{d_1} \mu \mu_\Delta^\rho e^{\gamma \bar{\delta}} |\xi(t-T)|} + \sqrt{\mu \frac{d_2}{\gamma d_1} T} \sup_{\ell \in [t-T, t]} |\vartheta(\ell)|.$$

Since (19) holds and  $T$  is arbitrarily large, one can choose  $T$  such that the corresponding  $\rho$  is so that  $\sqrt{\frac{d_2}{d_1} \mu \mu_\Delta^\rho e^{\gamma \bar{\delta}}} < 1$ . This concludes the proof.  $\square$

## C Proof of Lemma 3

Let us introduce a sequence:  $g_\ell = 4\ell\kappa$ . Then for all integer  $n > 0$ ,  $z(g_\ell) = S_\kappa^n z(g_{\ell-n})$ . Thus  $\Phi_\star(g_\ell, g_{\ell-n}) = S_\kappa^n$ . Let  $t \in \mathbb{R}$  and  $s \in \mathbb{R}$  be such that  $t > s \geq t - 4\kappa$ . Then

$$|\Phi_\star(t, s)| \leq e^{4\kappa \max\{|\Gamma_1|, |\Gamma_2|\}}. \quad (\text{C.1})$$

Now, let  $t \in \mathbb{R}$  and  $s \in \mathbb{R}$  be such that  $t + 4\kappa > s$ . Then there is  $\ell$  such that  $t \in [g_\ell, g_{\ell+1})$  and  $r \in \mathbb{N}$ ,  $r > 0$  such that  $s \in [g_{\ell-r-1}, g_{\ell-r})$ . Then

$$|\Phi_\star(t, s)| \leq e^{8\kappa \max\{|\Gamma_1|, |\Gamma_2|\}} |\Phi_\star(g_\ell, g_{\ell-r})|.$$

It follows that

$$|\Phi_\star(t, s)| \leq e^{8\kappa \max\{|\Gamma_1|, |\Gamma_2|\}} |S_\kappa^r|.$$

Since  $S_\kappa$  is Schur stable, there are  $c_\kappa > 1$  and  $d_\kappa > 0$  such that for all  $m \in \mathbb{N}$ ,  $|S_\kappa^m| \leq c_\kappa e^{-d_\kappa m}$ . Thus  $|\Phi_\star(t, s)| \leq e^{8\kappa \max\{|\Gamma_1|, |\Gamma_2|\}} c_\kappa e^{-d_\kappa r}$ . Now, notice that  $r \geq \frac{t-s}{4\kappa} - 2$ . Consequently,

$$|\Phi_\star(t, s)| \leq e^{8\kappa \max\{|\Gamma_1|, |\Gamma_2|\}} c_\kappa e^{2d_\kappa} e^{-d_\kappa \frac{t-s}{4\kappa}}. \quad (\text{C.2})$$

From (C.1) and (C.2), we deduce that for all  $t \geq s$ ,

$$|\Phi_\star(t, s)| \leq e^{8\kappa \max\{|\Gamma_1|, |\Gamma_2|\}} c_\kappa e^{2d_\kappa} e^{-d_\kappa \frac{t-s}{4\kappa}}. \quad (\text{C.3})$$

This allows us to conclude that (22) is satisfied.

Now, by integrating (21), we obtain that for all  $t \geq T$ ,

$$\begin{aligned} |z(t)| &= \left| \Phi_\star(t, t-T)z(t-T) + \int_{t-T}^t \Phi_\star(t, \ell) \varrho(\ell) d\ell \right| \\ &\leq p_1 e^{-p_2 T} |z(t-T)| + \int_{t-T}^t p_1 e^{-p_2(t-\ell)} d\ell \sup_{\ell \in [t-T, t]} |\varrho(\ell)| \end{aligned}$$

where the last inequality is a consequence of (22).  $\square$
