L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

# CATALECTICANT INTERSECTIONS AND CONFINEMENT OF DECOMPOSITIONS OF FORMS

ELENA ANGELINI, CRISTIANO BOCCI, LUCA CHIANTINI

ABSTRACT. We introduce the notion of confinement of decompositions for forms or vector of forms. The confinement, when it holds, lowers the number of parameters that one needs to consider, in order to find all the possible decompositions of a given set of data. With the technique of confinement, we obtain here two results. First, we give a new, shorter proof of a result by London ([21]) that 3 general plane cubics have 2 simultaneous Waring decompositions of rank 6. Then we compute, with the software Bertini, that 4 general plane quartics have 18 different decompositions of rank 10 (a result which was not known before).

Keywords. Waring decomposition; unidentifiable case; elliptic curve; catalecticant map; real rank.  
AMS Classification. 14N07; 14N05; 15A69; 14P05; 14Q99.

## 1. INTRODUCTION

A classical geometric approach for the study of the number of minimal decompositions of general tensors, in terms of rank 1 elements, goes back to Terracini and has been pointed out in [10] and [11]. The method is based on the observation that when a tensor of *sub-generic rank* has several minimal decompositions, then all the corresponding finite sets are bounded to specific sub-varieties, the *contact loci* of the variety  $X$  of rank 1 tensors. Since contact loci determine families of degenerate varieties that cover  $X$ , their existence has many geometric consequences, so that one can detect the existence of contact loci by analyzing the structure of  $X$ .

Families of sub-varieties which determine a special behavior are rather natural in interpolation theory. For interpolation problems on the plane, Segre's conjecture and its many modern variants predict that the superabundance of linear systems with prescribed singularities is equivalent to the existence of special varieties passing through sets of points (see e.g. [14]). Segre's idea that sub-varieties can determine special behavior for interpolation problems has been generalized in higher dimensional spaces by the second author, who introduced the notion of *special effect varieties* (see [8]). These varieties are responsible for the existence of interpolating linear systems whose dimension is higher than the expected value. The strict connection between superabundant interpolating systems for finite sets of points of multiplicity 2 and unexpected number of minimal decompositions is described in details in Section 2 of [10]. It turns out that an unexpected number of minimal decompositions implies the existence of positive dimensional contact loci, which are degenerate subvarieties of Segre or Veronese varieties, and conversely. Theorem 2.9 of [10] shows that contact loci provide the first examples of special effect varieties, for multiplicity 2 interpolation problems.

Terracini's idea cannot be extended to tensors of generic rank. Indeed, contact loci are defined by hyperplanes which are tangent at  $r$  points to the variety  $X$  of rank 1 objects, where  $r$  is the value of the rank under analysis. By definition, if  $r$  is the *generic rank*, then there are no hyperplanes tangent to  $X$  at  $r$  points, thus the notion of contact locus is meaningless for such value of  $r$ .

On the other hand, in the study of tensors  $T$  of generic rank, as soon as the number of minimal decompositions is small, then special sub-varieties that enclose all possible decompositions of  $T$  arise quite naturally in many examples (built both theoretically or with the aid of computer algebra packages). In this respect, an evidence that families of degenerate sub-varieties play a fundamental role is explained in the paper of Ciliberto and Russo [15], where degenerate rational curves are shown to determine the uniqueness of secant varieties through generic points, for some special classes of varieties  $X$  (see also [23], Corollary 5.4 and Remark 5.5).

One can guess that special sub-varieties are responsible for all special behaviors of the decompositions of a general tensor of rank  $r$  (note that for sub-generic ranks a special behavior means to have more than one minimal decomposition, while for the generic rank it means that the number of decompositions is small).

In the case of symmetric tensors  $f$  defined over a field  $\mathbb{F}$ , which will be identified with forms (homogeneous polynomials), there exists another approach that can produce sub-varieties bounding the decompositions of  $f$ . Indeed, for a degree  $d$  form  $f$  in  $n+1$  variables over  $\mathbb{F}$ , the contraction by  $f$  determines a map  $C_f$  (the *catalecticant map* of [19]) from the space of polynomial derivatives of order  $h$ , which can be identified with  $(\text{Sym}^h \mathbb{F}^{n+1})^\vee$ , to the space of forms of degree  $d-h$ . If  $f = \lambda_1 L_1^d + \dots + \lambda_k L_k^d$  is a Waring decomposition (the  $L_i$ 's and  $\lambda_i$ 's being, respectively, linear forms and scalars), then it is immediate to see that  $\mathbb{P}(\text{im}(C_f))$  sits into the span  $\Lambda$  of the powers  $[L_1^{d-h}], \dots, [L_k^{d-h}]$  in the space of forms of degree  $d-h$ . If the matrix of  $C_f$  has rank  $k$  and the  $[L_i]$ 's are linearly independent, then  $\mathbb{P}(\text{im}(C_f)) = \Lambda$ . Thus, for any other Waring decomposition  $f = \mu_1 M_1^d + \dots + \mu_k M_k^d$ , the images of the  $M_i$ 's under the  $d-h$  Veronese map are contained in the intersection of  $\Lambda$  with the corresponding Veronese variety  $X_{d-h}^n$ .

The intersection  $\Lambda \cap X_{d-h}^n$  has been studied until now only in order to prove that a form  $f$  is *identifiable*, i.e. its minimal Waring decomposition is unique. Namely, in the previous setting, if  $\Lambda \cap X_{d-h}^n$  consists of  $k$  points, then the uniqueness (modulo scaling and reordering) follows immediately, for a specific  $f$ . See e.g. [22] for an account of the method.

We propose to extend the method to the case where the intersection  $Y = \Lambda \cap X_{d-h}^n$  is not finite, but yet  $Y$  is a special subvariety of the space of tensors of rank 1. Since, in our setting, all the minimal decompositions of  $f$  must lie on  $Y$  and  $f$  itself is a point in the projective span of  $Y$ , then if we can compute the number of secant spaces to  $Y$  passing through a general point of the span, then we get the number of different Waring decompositions of a general  $f$ .

We present two cases in which the method yields interesting conclusions.

First (see Theorem 4.4) we analyze the simultaneous decompositions of 3 forms of degree 3 in 3 variables. In this case, following [4] Section 2.2, we know that the variety of elements of rank 1 corresponds to the Segre-Veronese embedding of  $\mathbb{P}^2 \times \mathbb{P}^2$  of bi-degree  $(1, 3)$ . This case has been classical considered by London in [21]. London used a direct method for the analysis of the net of quadrics, to determine that a general triple of cubic forms in 3 variables has two minimal simultaneous decompositions. London's approach is so involved that the result has been fully reconsidered and proved by Scorza in [24]. We present a new, elegant proof of London's result, which makes use of our analysis.

We observe that the analysis easily extends to simultaneous decompositions of forms of degrees  $3, 3, 3, 2, \dots, 2$  in 3 variables (see Corollary 4.6). Also in this case, we get that the number of such minimal decompositions is still 2. The result stated in Corollary 4.6 holds, in particular, for the case of quadruples of degrees  $3, 3, 3, 2$  in 3 variables (see Proposition 4.6); this case has been analyzed only recently by Galuppi, Mella, Ottaviani and the first author in [4] Section 4, where, after a

computer aided analysis by means of the software Bertini ([7]), it is conjectured that the number of simultaneous decompositions is 2. We can prove that the guess is correct.

In all these situations, the intersection variety  $Y$  that we find via the catalecticant map (which has the role of a *special effect variety* for our Waring problem) is an elliptic normal curve. Thus we conclude that the number of minimal decompositions is 2, since elliptic normal curves are known to have two secant spaces through a general point of the span (see Proposition 5.2 of [10]).

Let us notice that, even for specific tensors or polynomial vectors  $f$ , if the catalecticant map determines an intersection variety  $Y \subsetneq X$ , then the study of the Waring decompositions of  $f$  is reduced to the study of secant spaces to  $Y$  passing through  $f$ . When the variety  $Y$  is well known, we get in this way a lot of information. For instance, when  $Y$  is an elliptic curve (see also Example 7.2), by means of the main result Theorem 4.2 in [2] we can deduce the uniqueness of simultaneous decompositions of 3 cubics in three variables, *over the real field*  $\mathbb{R}$ , in a non-empty euclidean open subset.

Next (see Theorem 6.5) we analyze the simultaneous decomposition of 4 general forms of degree 4 in 3 variables. In this case, following [4] Section 2.2, we know that the simultaneous rank is 10, and the variety of elements of rank 1 corresponds to the Segre-Veronese embedding of  $\mathbb{P}^3 \times \mathbb{P}^2$  of bi-degree (1, 4). The number of simultaneous decompositions of a general vector of 4 quartics was previously unknown: a direct computational approach did not succeed in providing the number. We use the confinement to a general 3-fold section of the Segre embedding of  $\mathbb{P}^3 \times \mathbb{P}^2$  (whose birational description is the target of the (short) Section 5) to decrease the number of parameters. In this new setting, the software Bertini can compute in seconds that the number of different simultaneous Waring decomposition is 18 (all the computations have been done by means of Desktop PC - Windows 8 operating system x64 - Intel Core i5 CPU 1.70 GHz - 4 GB RAM).

As usual, similar computations by Bertini do not provide a theoretical proof that the number of decompositions is 18, but they give us a strong evidence of the result. See [18] for a discussion on the reliability of Bertini's computations. In Section 6 we will distinguish between theoretically defined results and results for which direct computations provide an extremely strong evidence by putting in front of them an asterisk \* (see e.g. Theorem\* 6.5).

As above, we observe that the analysis easily extends to simultaneous decompositions of forms of degrees 4, 4, 4, 4, 3,  $\dots$ , 3 in 3 variables (see Corollary 6.7). It is immediate to get that the number of such minimal decompositions is 18 in this case too.

Let us observe that when  $m > 4$ , for vectors of  $m$  forms of degree  $m$  in 3 variables the catalecticant confinement of decompositions does not hold, so we cannot decrease the number of parameters as before. We believe, however, that many other interesting initial cases of decompositions of forms or vector of forms can be handled with our technique.

The paper is structured as follows. In section 2 we introduce the simultaneous Waring decompositions, recalling the main notations and definitions (for a detailed description we refer to [4]). In section 3 we show how elliptic normal curves interact with the varieties of rank 1 elements introduced in Example 2.9 and Example 2.11. In section 4 we explain how certain catalecticant maps combine with elliptic normal curves to prove our Theorem 4.4. Section 5 is devoted to the description of linear sections of the Segre embedding of  $\mathbb{P}^3 \times \mathbb{P}^2$ . Section 6 is devoted to the determine the evidence that 4 plane quartics have 18 different decompositions of rank 10.

## 2. SIMULTANEOUS WARING DECOMPOSITIONS

Let  $\mathbb{F}$  be either the complex or real field. Let  $n, r \in \mathbb{N}$  and let  $a_1, \dots, a_r \in \mathbb{N}$ . Inside of  $\mathbb{F}[x_0, \dots, x_n]$ , which denotes the space of forms in  $n+1$  variables with coefficients in  $\mathbb{F}$ , we consider the elements of degree  $a_j$ , that is the sub-space  $\mathbb{F}[x_0, \dots, x_n]_{a_j} \cong \text{Sym}^{a_j} \mathbb{F}^{n+1}$ , for  $j \in \{1, \dots, r\}$ .

**Definition 2.1.** (See Section 4 of [4]) A *polynomial vector* (or *multiform*) is a vector  $f = (f_1, \dots, f_r)$  such that, for all  $j \in \{1, \dots, r\}$ ,  $f_j \in \mathbb{F}[x_0, \dots, x_n]_{a_j}$ .

A polynomial vector  $f$  is said to be *general* if each component  $f_j$  is a general element of  $\mathbb{F}[x_0, \dots, x_n]_{a_j}$ .

**Definition 2.2.** A *simultaneous Waring decomposition* of  $f$  over  $\mathbb{F}$  is given by linear forms  $\ell_1, \dots, \ell_k \in \mathbb{F}[x_0, \dots, x_n]_1$  and scalars  $(\lambda_1^j, \dots, \lambda_k^j) \in \mathbb{F}^k - \{\underline{0}\}$ ,  $j \in \{1, \dots, r\}$ , such that

$$f_j = \lambda_1^j \ell_1^{a_j} + \dots + \lambda_k^j \ell_k^{a_j}$$

for all  $j \in \{1, \dots, r\}$ , or, in vector notation,

$$(2.1) \quad f = \sum_{i=1}^k (\lambda_i^1 \ell_i^{a_1}, \dots, \lambda_i^r \ell_i^{a_r}).$$

The minimum number of summands  $k$  in a simultaneous Waring decomposition of  $f$  over  $\mathbb{F}$  is called the *rank* of  $f$  over  $\mathbb{F}$ . In particular, any summand in (2.1) has rank 1 over  $\mathbb{F}$ .

**Remark 2.3.** If  $f$  is a polynomial vector over  $\mathbb{R}$ , then the rank of  $f$  over  $\mathbb{R}$  is greater or equal to the rank of  $f$  over  $\mathbb{C}$ .

**Definition 2.4.** If  $f$  admits a unique presentation (resp. several presentations) over  $\mathbb{F}$  as in (2.1), then  $f$  is said to be *identifiable* (resp. *unidentifiable*) over  $\mathbb{F}$ .

Let us denote by  $\mathbb{P}^n = \mathbb{P}_{\mathbb{C}}^n$  the  $n$ -dimensional complex projective space.

**Remark 2.5.** According to Section 2.2 of [4], from a geometric point of view the variety of rank 1 polynomial vectors over  $\mathbb{C}$  with parameters  $(n, r; a_1, \dots, a_r)$  is the projective bundle

$$X_{a_1, \dots, a_r}^n = \mathbb{P}(\mathcal{O}_{\mathbb{P}^n}(a_1) \oplus \dots \oplus \mathcal{O}_{\mathbb{P}^n}(a_r)) \subset \mathbb{P}(H^0(\mathcal{O}_{\mathbb{P}^n}(a_1) \oplus \dots \oplus \mathcal{O}_{\mathbb{P}^n}(a_r))) = \mathbb{P}^{N-1}$$

where  $N = \sum_{j=1}^r \binom{a_j+n}{a_j}$ . Being the projectivization of a vector bundle of rank  $r$  over  $\mathbb{P}^n$ , then  $X_{a_1, \dots, a_r}^n$  has projective dimension  $r+n-1$  ([17], Ex. II.7.10). This immersion corresponds to the canonical invertible sheaf  $\mathcal{O}_{X_{a_1, \dots, a_r}^n}(1)$ . If a polynomial vector  $f \in \mathbb{P}^{N-1}$  can be written as in (2.1), then  $f$  belongs to  $S^k(X_{a_1, \dots, a_r}^n)$ , the *k-secant variety* of  $X_{a_1, \dots, a_r}^n$ . We refer to [20] for basics about secant varieties and the defectivity problem.

According to [4], we give the following:

**Definition 2.6.** The set of parameters  $(n, r; a_1, \dots, a_r)$  yields a *perfect case* if

$$(2.2) \quad N = k(\dim(X_{a_1, \dots, a_r}^n) + 1).$$

**Remark 2.7.** Throughout the paper we assume to be in a perfect case, i.e.  $k$  is equal to the quotient  $N/(\dim(X_{a_1, \dots, a_r}^n) + 1)$  and  $S^k(X_{a_1, \dots, a_r}^n)$  is expected to fill the ambient space  $\mathbb{P}^{N-1}$ . Moreover, as stated in [10], the general fibre of the *k-secant map*

$$p_{X_{a_1, \dots, a_r}^n}^k : S_{X_{a_1, \dots, a_r}^n}^k \rightarrow S^k(X_{a_1, \dots, a_r}^n)$$

where  $S_{X_{a_1, \dots, a_r}^k}^k$  denotes the *abstract  $k$ -secant variety* of  $X_{a_1, \dots, a_r}^n$ , is expected to be finite, that is there are only finitely many projective spaces of dimension  $k-1$  which are  $k$ -secant to  $X_{a_1, \dots, a_r}^n$  and pass through the general polynomial vector  $f \in \mathbb{P}^{N-1}$ . Therefore, in this case, we expect finitely many simultaneous Waring decompositions for  $f$ .

**Example 2.8.** In the classical Waring setting, i.e. when  $r = 1$ , if, for simplicity,  $a_1 = d$ , then the variety under investigation is

$$X_d^n = \mathbb{P}(\mathcal{O}_{\mathbb{P}^n}(d)) = \nu_d(\mathbb{P}^n) \subset \mathbb{P}^{\binom{d+n}{n}-1}$$

where  $\nu_d : \mathbb{P}^n \rightarrow \mathbb{P}^{\binom{d+n}{n}-1}$  is the Veronese embedding of  $\mathbb{P}^n$  of degree  $d$ .

**Example 2.9.** Assume that  $n = 2$ ,  $r = 3$ ,  $a_1 = a_2 = a_3 = 3$ . We will refer to this case as *London's case*, because it was studied by London in [21].

We focus on the 4-dimensional projective bundle

$$X_{3,3,3}^2 = \mathbb{P}(\mathcal{O}_{\mathbb{P}^2}(3)^{\oplus 3}) \subset \mathbb{P}(H^0(\mathcal{O}_{\mathbb{P}^2}(3)^{\oplus 3})) = \mathbb{P}^{29}.$$

The condition (2.2) is satisfied by  $k = 6$ . We note that

$$(2.3) \quad X_{3,3,3}^2 \cong \mathbb{P}(\mathcal{O}_{\mathbb{P}^2}(1)^{\oplus 3} \otimes \mathcal{O}_{\mathbb{P}^2}(2)) \cong \mathbb{P}(\mathcal{O}_{\mathbb{P}^2}^{\oplus 3} \otimes \mathcal{O}_{\mathbb{P}^2}(3)).$$

It is a standard fact that the projective bundle  $X_{1,1,1}^2 = \mathbb{P}(\mathcal{O}_{\mathbb{P}^2}(1)^{\oplus 3})$  is isomorphic to  $\text{Seg}(\mathbb{P}^2 \times \mathbb{P}^2) \subset \mathbb{P}^8$ , where  $\text{Seg}$  denotes the Segre embedding (see e.g. Section 2.2 of [4]). Namely, let us choose a  $\mathbb{P}^2$  associated to one of the three  $\mathcal{O}_{\mathbb{P}^2}(1)$ 's and an element  $\phi \in \text{Aut}(\mathbb{P}^2)$  with no fixed points: if, for any  $P \in \mathbb{P}^2$ , we consider the projective plane  $\langle P, \phi(P), \phi(\phi(P)) \rangle$ , we get an image of  $\mathbb{P}^2 \times \mathbb{P}^2$ .

By using (2.3), it turns out that  $X_{3,3,3}^2$  is the image of the embedding  $i_{3,3,3}^2$  of  $X_{1,1,1}^2$  in  $\mathbb{P}^{29}$  given by divisors of type  $(1, 3) = (3, 3) - (2, 0)$  over  $\text{Seg}(\mathbb{P}^2 \times \mathbb{P}^2)$ . We observe that a divisor of type  $(2, 0)$  over  $\text{Seg}(\mathbb{P}^2 \times \mathbb{P}^2)$  is defined by the Segre product of  $C \times \mathbb{P}^2$ , where  $C \subset \mathbb{P}^2$  is a divisor of degree 2, i.e. a conic. Since  $C = \nu_2(\mathbb{P}^1)$  is the image of the quadratic Veronese embedding of  $\mathbb{P}^1$ , we have that  $\text{Seg}(C \times \mathbb{P}^2)$  corresponds to an embedding of  $\mathbb{P}^1 \times \mathbb{P}^2$ , which is usually called the Segre-Veronese embedding. Thus  $i_{3,3,3}^2$  is given by cubic hypersurfaces of  $\mathbb{P}^8$  containing  $\text{Seg}(C \times \mathbb{P}^2)$ , where  $C \subset \mathbb{P}^2$  is a chosen conic.

**Remark 2.10.** With the aid of an algorithm based on Terracini's lemma [26] and described in Section 4 of [4], we know that the secant variety  $S^6(X_{3,3,3}^2)$  fills the ambient space  $\mathbb{P}^{29}$ , as expected. Thus, according to Remark 2.7, the general polynomial vector with parameters  $(n, r; a_1, \dots, a_r) = (2, 3; 3, 3, 3)$  has finitely many simultaneous Waring decompositions with  $k = 6$ .

**Example 2.11.** In the case considered in Corollary 4.6 we have that  $n = 2$ ,  $r \geq 4$ ,  $a_j = 2$  for  $j \geq 4$ ,  $a_1 = a_2 = a_3 = 3$  and the projective bundle under investigation is

$$X_{3,3,3,2,\dots,2}^2 = \mathbb{P}(\mathcal{O}_{\mathbb{P}^2}(3)^{\oplus 3} \oplus \mathcal{O}_{\mathbb{P}^2}(2)^{\oplus 3}) \subset \mathbb{P}(H^0(\mathcal{O}_{\mathbb{P}^2}(3)^{\oplus 3} \oplus \mathcal{O}_{\mathbb{P}^2}(2)^{\oplus r-3})) = \mathbb{P}^{29+6(r-3)}$$

which still gives a perfect case if  $k = 6$ . We note that

$$(2.4) \quad X_{3,3,3,2,\dots,2}^2 \cong \mathbb{P}((\mathcal{O}_{\mathbb{P}^2}(1)^{\oplus 3} \oplus \mathcal{O}_{\mathbb{P}^2}^{\oplus r-3}) \otimes \mathcal{O}_{\mathbb{P}^2}(2)) \cong \mathbb{P}((\mathcal{O}_{\mathbb{P}^2}^{\oplus 3} \oplus \mathcal{O}_{\mathbb{P}^2}(-1)^{\oplus r-3}) \otimes \mathcal{O}_{\mathbb{P}^2}(3)).$$

As a consequence of the argument used in Example 2.9,  $X_{1,1,1,0,\dots,0}^2 = \mathbb{P}(\mathcal{O}_{\mathbb{P}^2}(1)^{\oplus 3} \oplus \mathcal{O}_{\mathbb{P}^2}^{\oplus r-3}) \subset \mathbb{P}^{r+5}$  in  $\mathbb{P}^{29+6(r-3)}$  can be described as the cone with vertex a linear space  $L \cong \mathbb{P}^{r-4}$  over the Segre variety  $\text{Seg}(\mathbb{P}^2 \times \mathbb{P}^2) \cong X_{1,1,1}^2 \subset \mathbb{P}^8$ , that is  $X_{1,1,1,0,\dots,0}^2 = C_L(X_{1,1,1}^2)$ . Indeed, the summand  $\mathcal{O}_{\mathbb{P}^2}^{\oplus r-3}$  gives the vertex  $L$  of the cone.

By using (2.4),  $X_{3,3,3,2,\dots,2}^2$  is the image of the embedding  $i_{3,3,3,2,\dots,2}^2$  of  $X_{1,1,1,0,\dots,0}^2$  in  $\mathbb{P}^{29+6(r-3)}$ ,

defined by divisors of type  $(1, 3) = (3, 3) - (2, 0)$  over  $C_L(\text{Seg}(\mathbb{P}^2 \times \mathbb{P}^2))$ , that is, extending the argument of Example 2.9, by cubic hypersurfaces of  $\mathbb{P}^{r+5}$  (which cut divisors of type  $(3, 3)$  over  $X_{1,1,1,0,\dots,0}^2$ ) containing the cone  $C_L(\text{Seg}(C \times \mathbb{P}^2))$ , where  $C \subset \mathbb{P}^2$  is a conic.

**Example 2.12.** Assume that  $n = 2$ ,  $r = 4$ ,  $a_1 = a_2 = a_3 = a_4 = 4$ .

We focus on the 5-dimensional projective bundle

$$X_{4,4,4,4}^2 = \mathbb{P}(\mathcal{O}_{\mathbb{P}^2}(4)^{\oplus 4}) \subset \mathbb{P}(H^0(\mathcal{O}_{\mathbb{P}^2}(4)^{\oplus 4})) = \mathbb{P}^{59}.$$

The condition (2.2) is satisfied by  $k = 10$ . We note that

$$(2.5) \quad X_{4,4,4,4}^2 \cong \mathbb{P}(\mathcal{O}_{\mathbb{P}^2}^{\oplus 4} \otimes \mathcal{O}_{\mathbb{P}^2}(4)).$$

As in Example 2.9 or by Section 2.2 of [4], the projective bundle  $X_{1,1,1,1}^2 = \mathbb{P}(\mathcal{O}_{\mathbb{P}^2}(1)^{\oplus 4})$  is isomorphic to  $\text{Seg}(\mathbb{P}^3 \times \mathbb{P}^2) \subset \mathbb{P}^{11}$ .

By using (2.5), it turns out that  $X_{4,4,4,4}^2$  is the image of the embedding  $i_{4,4,4,4}^2$  of  $X_{1,1,1,1}^2$  in  $\mathbb{P}^{59}$  given by divisors of type  $(1, 4)$  over  $\text{Seg}(\mathbb{P}^3 \times \mathbb{P}^2)$ .

**Remark 2.13.** With the aid of an algorithm based on Terracini's lemma [26] and described in Section 4 of [4], we know that the secant variety  $S^{10}(X_{4,4,4,4}^2)$  fills the ambient space  $\mathbb{P}^{59}$ , as expected. Thus, according to Remark 2.7, the general polynomial vector with parameters  $(n, r; a_1, \dots, a_r) = (2, 4; 4, 4, 4, 4)$  has finitely many simultaneous Waring decompositions with  $k = 10$ .

We end this introductory section with the definition of *catalecticant map* associated to polynomial vectors, according to [19].

**Definition 2.14.** Let  $f = (f_1, \dots, f_r)$  be a general polynomial vector such that  $f_j \in \mathbb{C}[x_0, x_1, x_2]_d$ , for  $j = 1, \dots, r$ . For any  $h$ , identify the dual space  $(\text{Sym}^h \mathbb{C}^3)^\vee$  as the space of polynomial derivatives in 3 variables of order  $h$ . The map

$$C_f^h : (\text{Sym}^h \mathbb{C}^3)^\vee \rightarrow (\text{Sym}^{d-h} \mathbb{C}^3)^{\oplus r}$$

given by the contraction by  $f$  is called the *catalecticant map* of order  $h$  associated to  $f$ . When  $h = d - 1$ , we will write simply  $C_f$  instead of  $C_f^{d-1}$ .

**Remark 2.15.**  $C_f^h$  is a linear map. The associated matrix, which, by abuse, we will denote again by  $C_f^h$ , has 0-degree entries and is divided into  $r$  blocks, i.e.:

$$(2.6) \quad C_f^h = \begin{pmatrix} DD_1 \\ \dots \\ DD_r \end{pmatrix}$$

where  $DD_j$  is a  $\binom{d-h+2}{2} \times \binom{h+2}{2}$  block such that in each column there are the coefficients of one derivative of order  $h$  of  $f_j$ .

As explained in the Introduction, every catalecticant map provides good candidates for the confinement of the decompositions of a polynomial vector, at least when it does not surject. In the sequel, we will use only catalecticant maps of order  $d - 1$ , for vectors of forms of degree  $d$ , which will be sufficient for our purposes.

### 3. ELLIPTIC NORMAL CURVES

An *elliptic normal curve*  $\mathcal{C} \subset \mathbb{P}^m$  is an irreducible, smooth curve of genus 1 and degree  $m + 1$  that is not degenerate. As for any curve (see Remark 3.1 of [9]), for all  $h \in \mathbb{N}$ , the  $h$ -secant variety  $S^h(\mathcal{C})$  of  $\mathcal{C}$  has the expected dimension  $\dim S^h(\mathcal{C}) = \min\{2h - 1, m\}$ .

Recall that the *rank* of a point  $P \in \langle \mathcal{C} \rangle = \mathbb{P}^m$  over  $\mathbb{C}$  with respect to  $\mathcal{C}$  is the minimal number of points of  $\mathcal{C}$  needed to generate a projective space over  $\mathbb{C}$  containing  $P$ .

**Remark 3.1.** If  $\mathcal{C} \subset \mathbb{P}^{2k-1}$  is an elliptic normal curve of even degree  $m + 1 = 2k$  and  $P \in \langle \mathcal{C} \rangle = \mathbb{P}^{2k-1}$  is a general point, then the rank of  $P$  over  $\mathbb{C}$  with respect to  $\mathcal{C}$  is  $k$ . Therefore the value  $k$  corresponds to the generic rank and provides a perfect case in the sense of Definition 2.6 and Remark 2.7.

In the specific case of elliptic curves, one knows the number of decompositions of a general tensor of generic rank. Namely, the following holds:

**Proposition 3.2** (Chiantini-Ciliberto, 2006, [10]). *The number of  $k$ -secant  $(k - 1)$ -spaces to an elliptic normal curve  $\mathcal{C}$  of degree  $2k$  in  $\mathbb{P}^{2k-1}$ , passing through the general point of  $\mathbb{P}^{2k-1}$ , is 2.*

With the notation of Example 2.9 we prove the following:

**Proposition 3.3.** *The intersection of  $X_{1,1,1}^2 = \text{Seg}(\mathbb{P}^2 \times \mathbb{P}^2)$  with a general linear space of dimension 5 in  $\mathbb{P}^8$  is an irreducible normal elliptic curve of degree 6. Thus, for a general choice of 6 points  $\tilde{p}_1, \dots, \tilde{p}_6 \in X_{1,1,1}^2$  there exists a unique (sextic) elliptic normal curve  $\mathcal{C}$  of  $\mathbb{P}^5$  passing through the points.*

*Proof.*  $X_{1,1,1}^2 = \text{Seg}(\mathbb{P}^2 \times \mathbb{P}^2)$  is smooth, irreducible and non-degenerate, of degree 6. Thus the intersection  $\mathcal{C}$  of  $X_{1,1,1}^2$  with a general linear space of dimension 5 is a smooth irreducible and non-degenerate curve of degree 6 in  $\mathbb{P}^5$  (apply consecutively the classical Bertini's Theorems, see [17] Theorem II.8.18 and Remark III.7.9.1). The fact that  $\mathcal{C}$  has genus 1 has been classically proved by Scorza in [25] (the classical notion of *variety with elliptic curve sections* means exactly that a general curve section of  $\text{Seg}(\mathbb{P}^2 \times \mathbb{P}^2)$  has genus 1).

The second claim follows because 6 general points  $\tilde{p}_1, \dots, \tilde{p}_6$  of  $X_{1,1,1}^2$  span a general  $\mathbb{P}^5$  in  $\mathbb{P}^8$ , as  $X_{1,1,1}^2$  is non-degenerate.

Notice that the uniqueness of the elliptic normal curve  $\mathcal{C}$  of degree 6 through  $\tilde{p}_1, \dots, \tilde{p}_6$  follows by Bézout Theorem, since  $\text{Seg}(\mathbb{P}^2 \times \mathbb{P}^2)$  has degree 6, thus it cannot intersect a general  $\mathbb{P}^5$ , span of the 6 general points, in a curve of degree bigger than 6.  $\square$

**Remark 3.4.** A confirmation of the statement of Proposition 3.3 can be obtained also from a computational point of view, via the software system Macaulay2 [16] (for more details on the script see the ancillary file <https://arxiv.org/src/1911.07769v2/anc/CatIntConf.pdf>).

By extending the construction in the proof of Proposition 3.3 to cones, we obtain the following:

**Proposition 3.5.** *Let  $p_1, \dots, p_6 \in X_{1,1,1,0,\dots,0}^2$  be general points. There exists a unique (sextic) elliptic normal curve  $\mathcal{C}_1$  of  $\mathbb{P}^5$  passing through  $p_1, \dots, p_6$ .*

*Proof.* Since, according to Example 2.11,  $X_{1,1,1,0,\dots,0}^2 = \mathcal{C}_L(X_{1,1,1}^2)$ , then exactly the same proof given in Proposition 3.3 for  $X_{1,1,1}^2$  works.  $\square$

As a consequence of Example 2.9 and Proposition 3.3, we get the following:

**Proposition 3.6.** *Let  $\tilde{q}_1, \dots, \tilde{q}_6 \in X_{3,3,3}^2$  be general points. There exists a unique elliptic normal curve  $\mathcal{C}_2$  of  $\mathbb{P}^{11}$  passing through  $\tilde{q}_1, \dots, \tilde{q}_6$ .*

*Proof.* Let  $\tilde{p}_1, \dots, \tilde{p}_6 \in X_{1,1,1}^2$  such that  $\tilde{q}_j = i_{3,3,3}^2(\tilde{p}_j)$ ,  $j \in \{1, \dots, 6\}$  and let  $\mathcal{C}$  be the sextic elliptic normal curve corresponding to  $\tilde{p}_1, \dots, \tilde{p}_6$  in the sense of Proposition 3.3. We claim that  $\mathcal{C}_2 = i_{3,3,3}^2(\mathcal{C})$  is an elliptic normal curve of degree  $12 = 18 - 6$ . Namely,  $\mathcal{C}_2$  is smooth irreducible of genus 1 because it is isomorphic to  $\mathcal{C}$ . Moreover, since  $i_{3,3,3}^2$  is defined by means of cubics and  $\deg \mathcal{C} = 6$ , and since the base locus of  $i_{3,3,3}^2$  is  $\text{Seg}(C \times \mathbb{P}^2)$ , where  $C$  is a conic curve (see Example 2.11), then the degree of  $\mathcal{C}_2$  is 18 minus the degree of the intersection  $\text{Seg}(C \times \mathbb{P}^2) \cap \langle \mathcal{C} \rangle$ . Notice that the intersection is 0-dimensional, since the points are general and  $\text{Seg}(C \times \mathbb{P}^2)$  is a 4-fold in  $\mathbb{P}^8$  while  $\langle \mathcal{C} \rangle = \langle \tilde{p}_1, \dots, \tilde{p}_6 \rangle \cong \mathbb{P}^5$ . Since  $\deg(\text{Seg}(C \times \mathbb{P}^2)) = \deg(C \times \mathbb{P}^2) = 2 \cdot \deg(\mathbb{P}^1 \times \mathbb{P}^2) = 6$ , we get that  $\deg \mathcal{C}_2 = 18 - 6 = 12$ , as claimed. We remark that  $\langle \mathcal{C}_2 \rangle = \mathbb{P}^{11}$ : indeed the dimension of the projective space spanned by  $\mathcal{C}_2$  can't exceed 11 by the Riemann-Roch Theorem (see [17], Theorem IV.1.3) and it can't be lower than 11, otherwise, through the general point of  $\langle \mathcal{C}_2 \rangle$  would pass infinitely many 6-secant spaces, which implies that, by Theorem 2.5 of [10], the secant variety  $S^6(X_{3,3,3}^2)$  is defective and this is not possible as explained in Remark 2.10.  $\square$

#### 4. THE CASE OF THREE TERNARY CUBICS

Let  $f = (f_1, f_2, f_3)$  be a general polynomial vector such that  $f_j \in \mathbb{C}[x_0, x_1, x_2]_3$ , for  $j \in \{1, 2, 3\}$ . Consider the catalecticant map  $C_f$ , defined by derivatives of order 2, associated to  $f$  (see Definition 2.14)

$$C_f : (\text{Sym}^2 \mathbb{C}^3)^\vee \rightarrow (\text{Sym}^1 \mathbb{C}^3)^{\oplus 3}.$$

As pointed out in Remark 2.15, the associated  $9 \times 6$  matrix (that we call again  $C_f$ ) is divided into 3 blocks of type  $3 \times 6$ :

$$(4.1) \quad C_f = \begin{pmatrix} DD_1 \\ DD_2 \\ DD_3 \end{pmatrix}$$

We have the following:

**Proposition 4.1.** *For a generic choice of  $f$  with  $(n, r; a_1, \dots, a_r) = (2, 3; 3, 3, 3)$  we have that:*

(i)  $C_f$  is an injective map;

(ii)  $\mathbb{P}(\text{im}(C_f))$  intersects  $X_{1,1,1}^2$  in a sextic elliptic normal curve.

*Proof.* Fix a Waring decomposition of  $f \in \mathbb{P}^{29}$  given by the points  $\tilde{q}_i = (\lambda_i^1 \ell_i^3, \lambda_i^2 \ell_i^3, \lambda_i^3 \ell_i^3) \in X_{3,3,3}^2$ , where we can assume, without loss of generality, that  $\ell_i = x_0 + \nu_i^1 x_1 + \nu_i^2 x_2$  for  $i \in \{1, \dots, 6\}$ .

Immediate direct computations show that

$$C_f = \left( \sum_{i=1}^6 C_i \quad \sum_{i=1}^6 \nu_i^1 C_i \quad \sum_{i=1}^6 \nu_i^2 C_i \quad \sum_{i=1}^6 \nu_i^1 \nu_i^1 C_i \quad \sum_{i=1}^6 \nu_i^1 \nu_i^2 C_i \quad \sum_{i=1}^6 \nu_i^2 \nu_i^2 C_i \right)$$

where

$$(4.2) \quad C_i = 6 \begin{pmatrix} \lambda_i^1 & \nu_i^1 \lambda_i^1 & \nu_i^2 \lambda_i^1 & \lambda_i^2 & \nu_i^1 \lambda_i^2 & \nu_i^2 \lambda_i^2 & \lambda_i^3 & \nu_i^1 \lambda_i^3 & \nu_i^2 \lambda_i^3 \end{pmatrix}^t, \quad i \in \{1, \dots, 6\}.$$

In order to work with general  $f$ , by semicontinuity we choose to assign random values to the  $\lambda_i^j$ 's and  $\nu_i^h$ 's,  $h \in \{1, 2\}$ ,  $i \in \{1, \dots, 6\}$ ,  $j \in \{1, 2, 3\}$  and we compute the corresponding  $f_1, f_2, f_3$ . Then we construct the matrix  $C_f$ : if its rank is 6, then we can conclude that (i) holds. This fact can be verified from a computational point of view via Macaulay2 (for more details on the script see the ancillary file

<https://arxiv.org/src/1911.07769v2/anc/CatIntConf.pdf>). As a consequence,  $\mathbb{P}(\text{im}(C_f)) \cong \mathbb{P}^5 \subset \mathbb{P}(\text{Sym}^1 \mathbb{C}^3)^{\oplus 3} \cong \mathbb{P}^8$  and, since  $X_{1,1,1}^2 \subset \mathbb{P}^8$  is 4-dimensional, then  $\dim(\mathbb{P}(\text{im}(C_f)) \cap X_{1,1,1}^2) = 1$ . By arguing as in the proof of Proposition 3.3 we get that the intersection curve has degree 6, as one can compute directly (see the instructions added to the previous script and provided in the ancillary file <https://arxiv.org/src/1911.07769v2/anc/CatIntConf.pdf>). Thus (ii) follows.  $\square$

Therefore we have the following:

**Proposition 4.2.** *Let  $f$  be a general polynomial vector with  $(n, r; a_1, \dots, a_r) = (2, 3; 3, 3, 3)$  and let  $\tilde{q}_i = (\lambda_i^1 \ell_i^3, \lambda_i^2 \ell_i^3, \lambda_i^3 \ell_i^3) \in X_{3,3,3}^2$ ,  $i \in \{1, \dots, 6\}$ , be the points of a simultaneous Waring decomposition of  $f$ . Then*

$$\mathbb{P}(\text{im } C_f) = \langle [\ell_1^\vee \otimes (\lambda_1^1, \lambda_1^2, \lambda_1^3)], \dots, [\ell_6^\vee \otimes (\lambda_6^1, \lambda_6^2, \lambda_6^3)] \rangle$$

where  $\ell_i^\vee$  denotes a representative vector of the point corresponding to  $\ell_i$  in the dual projective plane  $(\mathbb{P}^2)^\vee$  and  $[\ell_i^\vee \otimes (\lambda_i^1, \lambda_i^2, \lambda_i^3)]$  the equivalence class of  $\ell_i^\vee \otimes (\lambda_i^1, \lambda_i^2, \lambda_i^3)$  in  $\mathbb{P}^8$ , for  $i \in \{1, \dots, 6\}$ .

*Proof.* Without loss of generality, we can assume that  $\ell_i = x_0 + \nu_i^1 x_1 + \nu_i^2 x_2$ , for  $i \in \{1, \dots, 6\}$ . By means of equation (4.2), we get that

$$[C_i] = [(1, \nu_i^1, \nu_i^2) \otimes (\lambda_i^1, \lambda_i^2, \lambda_i^3)] = [\ell_i^\vee \otimes (\lambda_i^1, \lambda_i^2, \lambda_i^3)], \quad i \in \{1, \dots, 6\}.$$

Thus,  $\mathbb{P}(\text{im } C_f) \subset \langle [\ell_1^\vee \otimes (\lambda_1^1, \lambda_1^2, \lambda_1^3)], \dots, [\ell_6^\vee \otimes (\lambda_6^1, \lambda_6^2, \lambda_6^3)] \rangle$ . Since, by Proposition 4.1 part (i), the rank of  $C_f$  is generically 6, the previous inclusion is actually an equality, as desired.

A computational verification of this fact can be done via Macaulay2. For more details see the ancillary file <https://arxiv.org/src/1911.07769v2/anc/CatIntConf.pdf>.  $\square$

From Proposition 4.2 and Proposition 3.6, we get the following:

**Corollary 4.3.** *For all  $i \in \{1, \dots, 6\}$ ,  $[\ell_i^\vee \otimes (\lambda_i^1, \lambda_i^2, \lambda_i^3)]$  belongs to the sextic elliptic normal curve  $\mathcal{C} = \mathbb{P}(\text{im } C_f) \cap X_{1,1,1}^2$  and  $\tilde{q}_i = (\lambda_i^1 \ell_i^3, \lambda_i^2 \ell_i^3, \lambda_i^3 \ell_i^3)$  lies on the elliptic normal curve of degree 12  $\mathcal{C}_2 = i_{3,3,3}^2(\mathcal{C})$ .*

As a consequence we get:

**Theorem 4.4.** *The general  $f = (f_1, f_2, f_3)$  such that  $f_i \in \mathbb{C}[x_0, x_1, x_2]_3$ , for  $i \in \{1, 2, 3\}$ , has two simultaneous Waring decompositions with  $k = 6$  summands.*

*Proof.* Fix a Waring decomposition of  $f \in \mathbb{P}^{29}$  given by the points  $\tilde{q}_i = (\lambda_i^1 \ell_i^3, \lambda_i^2 \ell_i^3, \lambda_i^3 \ell_i^3) \in X_{3,3,3}^2$  for  $i \in \{1, \dots, 6\}$ . Thanks to Corollary 4.3, we get that  $\tilde{q}_1, \dots, \tilde{q}_6$  belong to an elliptic normal curve  $\mathcal{C}_2$  of degree 12 in  $X_{3,3,3}^2$ , which spans the  $\mathbb{P}^{11}$  where  $f$  lies. The two 6-secant spaces to  $\mathcal{C}_2$  containing  $f$ , that exist because of Proposition 3.2, determine the two required Waring decompositions of  $f$ .  $\square$

**Remark 4.5.** According to Example 2.9 we have  $X_{3,3,3}^2 \cong \text{Seg}(\mathbb{P}^2 \times \nu_3(\mathbb{P}^2))$ . Then Theorem 4.4 implies that the Veronese surface  $\nu_3(\mathbb{P}^2)$  is not  $(2, 6)$ -identifiable, in the sense of [6]. In particular, the general  $\mathbb{P}^2 \subset \langle P_1, \dots, P_6 \rangle$ , where  $P_1, \dots, P_6 \in \nu_3(\mathbb{P}^2)$  are independent points, is contained in one more  $\mathbb{P}^5$  6-secant to  $\nu_3(\mathbb{P}^2)$ , besides  $\langle P_1, \dots, P_6 \rangle$ . Therefore, the general linear system of ternary cubics  $\mathcal{E} \subset \mathbb{P}(H^0(\mathcal{O}_{\mathbb{P}^2}(3))^{\oplus 3})$  of dimension 2 and rank 6 is computed by exactly 2 sets of polynomial vectors of rank 1.

By combining Theorem 4.4 with the observation that the linear space of quadratic forms in three variables has dimension 6, we get:

**Corollary 4.6.** *For any  $r \geq 4$ , the general  $f = (f_1, f_2, f_3, f_4, \dots, f_r)$  such that  $f_i \in \mathbb{C}[x_0, x_1, x_2]_3$ ,  $i \in \{1, 2, 3\}$ , and  $f_i \in \mathbb{C}[x_0, x_1, x_2]_2$ ,  $i \in \{4, \dots, r\}$ , has two Waring decompositions with  $k = 6$  summands.*

*In particular for  $r = 4$ , the general  $f = (f_1, f_2, f_3, f_4)$  such that  $f_i \in \mathbb{C}[x_0, x_1, x_2]_3$ , for  $i \in \{1, 2, 3\}$ , and  $f_4 \in \mathbb{C}[x_0, x_1, x_2]_2$  has two simultaneous Waring decompositions with  $k = 6$  summands.*

*Proof.* It is immediate since the decompositions of a general vector  $(f_1, f_2, f_3)$  of cubics is given by powers of 6 general linear forms, whose squares generate the space of all conics.  $\square$

As we anticipated in section 1, Corollary 4.6 yields a proof for a conjecture stated in [4].

**Remark 4.7.** We notice that the arguments used to prove Theorem 4.4 extend in a natural way to get an alternative proof of Corollary 4.6. The main difference between the two cases is the role of cones, as stressed in Example 2.11. Indeed, fix a Waring decomposition of  $f \in \mathbb{P}^{29+6(r-3)}$  given by  $q_i = (\lambda_i^1 \ell_i^3, \lambda_i^2 \ell_i^3, \lambda_i^3 \ell_i^3, \lambda_i^4 \ell_i^2, \dots, \lambda_i^r \ell_i^2) \in X_{3,3,3,2,\dots,2}^2$ ,  $i \in \{1, \dots, 6\}$ . By generalizing Corollary 4.3, we can show that the *catalecticant map*

$$C_f : (\text{Sym}^2 \mathbb{C}^3)^\vee \rightarrow (\text{Sym}^1 \mathbb{C}^3)^{\oplus 3} \oplus \mathbb{C}^{\oplus r-3}$$

given by the contraction by  $f$ , is such that  $q_i$  belongs to the elliptic normal curve of degree 12

$$\mathcal{C}_3 = i_{3,3,3,2,\dots,2}^2(\mathbb{P}(\text{im } C_f) \cap X_{1,1,1,0,\dots,0}^2)$$

and  $f \in \langle \mathcal{C}_3 \rangle = \mathbb{P}^{11}$ . Thus, Proposition 3.2 allows us to conclude the proof.

## 5. THREEFOLD SECTIONS OF $\text{SEG}(\mathbb{P}^3 \times \mathbb{P}^2)$

In this section we consider  $X_{1,1,1,1}^2 = \text{Seg}(\mathbb{P}^3 \times \mathbb{P}^2)$  and our aim is to describe a general threefold section  $W$  of  $X_{1,1,1,1}^2$ .

We prove that  $W$  is rational and we describe a birational map  $\rho : \mathbb{P}^1 \times \mathbb{P}^2 \dashrightarrow W$ .

**Proposition 5.1.** *A general threefold section  $W$  of  $X_{1,1,1,1}^2 = \text{Seg}(\mathbb{P}^3 \times \mathbb{P}^2)$  is the image of  $\mathbb{P}^1 \times \mathbb{P}^2$  defined by divisors of type  $(1, 2)$  passing through 2 generic points.*

*Proof.* We need to define maps  $\rho_1 : \mathbb{P}^1 \times \mathbb{P}^2 \rightarrow \mathbb{P}^2$  and  $\rho_2 : \mathbb{P}^1 \times \mathbb{P}^2 \rightarrow \mathbb{P}^3$ . The map  $\rho_1$  is the straightforward projection to the second factor, given by divisors of type  $(0, 1)$ . The map  $\rho_2$  is the composition of the Segre embedding in  $\mathbb{P}^5$  with a general internal projection from two points of  $\text{Seg}(\mathbb{P}^1 \times \mathbb{P}^2)$ , i.e. the map given by divisors of type  $(1, 1)$  passing through two general points of  $\mathbb{P}^1 \times \mathbb{P}^2$ . Since  $\text{Seg}(\mathbb{P}^1 \times \mathbb{P}^2)$  is a threefold of degree 3 in  $\mathbb{P}^5$ , then  $\rho_2$  is birational. The sum  $\rho = \rho_1 + \rho_2$  is the required map. The fact that the image is contained in a 3-dimensional plane in  $\mathbb{P}^{11}$  is a straightforward computation.

By combining  $\rho$  with a change of coordinates and counting parameters, we obtain that a general threefold section of  $\text{Seg}(\mathbb{P}^3 \times \mathbb{P}^2)$  is the image of a map like  $\rho$ .  $\square$

By collecting Proposition 5.1 and Example 2.12, we get:

**Corollary 5.2.** *The image of a general threefold section  $W$  of  $X_{1,1,1,1}^2 = \text{Seg}(\mathbb{P}^3 \times \mathbb{P}^2)$  in the map  $i_{4,4,4,4}^2$  is the image of  $\mathbb{P}^1 \times \mathbb{P}^2$  in the map given by divisors of type  $(1, 5)$  passing through 2 generic points.*

6. THE CASE OF FOUR TERNARY QUARTICS

Let  $f = (f_1, f_2, f_3, f_4)$  be a general polynomial vector such that  $f_j \in \mathbb{C}[x_0, x_1, x_2]_4$ , for  $j \in \{1, 2, 3, 4\}$ . Consider the catalecticant map  $C_f$ , given by derivatives of order 3, associated to  $f$  (see Definition 2.14)

$$C_f : (\text{Sym}^3 \mathbb{C}^3)^\vee \rightarrow (\text{Sym}^1 \mathbb{C}^3)^{\oplus 4}.$$

As pointed out in Remark 2.15, the associated  $12 \times 10$  matrix  $C_f$  is divided into 4 blocks of order  $3 \times 10$

$$(6.1) \quad C_f = \begin{pmatrix} DD_1 \\ DD_2 \\ DD_3 \\ DD_4 \end{pmatrix}.$$

We have the following:

**Proposition 6.1.** *For a generic choice of  $f$  with  $(n, r, a_1, \dots, a_r) = (2, 4, 4, 4, 4, 4)$  we have that:*

- (i)  $C_f$  is an injective map;
- (ii)  $\mathbb{P}(\text{im}(C_f))$  intersects  $X_{1,1,1,1}^2$  in a general section of codimension 2, i.e. in a general threefold section.

*Proof.* The first claim follows from a computation which is absolutely equivalent with the one in the proof of Proposition 4.1. (See also the ancillary file to this paper <https://arxiv.org/src/1911.07769v2/anc/CatIntConf.pdf>.)

The second claim follows by counting parameters. □

Therefore we have the following:

**Corollary 6.2.** *Let  $f$  be a general polynomial vector with  $(n, r; a_1, \dots, a_r) = (2, 4; 4, 4, 4, 4)$  and let  $\tilde{q}_i = (\lambda_i^1 \ell_i^4, \lambda_i^2 \ell_i^4, \lambda_i^3 \ell_i^4, \lambda_i^4 \ell_i^4) \in X_{4,4,4,4}^2$ ,  $i \in \{1, \dots, 10\}$ , be the points of a simultaneous Waring decomposition of  $f$ .*

*Then for all  $i \in \{1, \dots, 10\}$ ,  $[\ell_i^\vee \otimes (\lambda_i^1, \lambda_i^2, \lambda_i^3, \lambda_i^4)]$  belongs to a general threefold section  $W = \mathbb{P}(\text{im } C_f) \cap X_{1,1,1,1}^2$  and  $\tilde{q}_i = (\lambda_i^1 \ell_i^4, \lambda_i^2 \ell_i^4, \lambda_i^3 \ell_i^4, \lambda_i^4 \ell_i^4)$  lies on the image  $i_{4,4,4,4}^2(W)$ .*

By collecting Corollary 6.2 and Corollary 5.2 we immediately get the following:

**Corollary 6.3.** *The number of simultaneous Waring decompositions with 10 summands of the general polynomial vector  $f$  such that  $(n, r; a_1, \dots, a_r) = (2, 4; 4, 4, 4, 4)$  equals the number of presentations with 10 summands of the general  $\tilde{f} \in \mathbb{P}^{39}$  ( $\tilde{f}$  is a polynomial of bi-degree  $(1, 5)$ ) vanishing at 2 fixed generic points  $P, Q \in \mathbb{P}^1 \times \mathbb{P}^2$ ) of type*

$$(6.2) \quad \tilde{f} = \sum_{i=1}^{10} g_i h_i^5$$

where  $g_i \in \mathbb{C}[s, t]_1$ ,  $h_i \in \mathbb{C}[y_0, y_1, y_2]_1$  and  $g_i h_i^5$  vanishes at  $P, Q$ , for any  $i \in \{1, \dots, 5\}$ .

Therefore our starting problem reduces to counting decompositions in the second case introduced in Corollary 6.3. In order to do that, by means of Bertini and Matlab software, we developed a procedure, which, inspired to the one introduced in the papers [4] and [1], allows us to prove from a computational point of view the following:

**Proposition\* 6.4.** *The general  $\tilde{f} \in \mathbb{P}^{39}$  admits 18 presentations with 10 summands as in (6.2), up to re-ordering and re-scaling.*

*Proof.* Let  $\tilde{f} \in \mathbb{P}^{39}$  be a general element and let  $\{s, t\}$  (respectively  $\{y_0, y_1, y_2\}$ ) be a set of homogeneous coordinates for  $\mathbb{P}^1$  (respectively for  $\mathbb{P}^2$ ). Without loss of generality, we choose  $P = [1, 0] \times [0, 0, 1]$  and  $Q = [0, 1] \times [0, 1, 0]$  as generic points in  $\mathbb{P}^1 \times \mathbb{P}^2$ . If we write the polynomials in (6.2) as  $g_{i+1} = v_{4i+2}s + v_{4i+3}t$  and  $h_{i+1} = y_0 + v_{4i}y_1 + v_{4i+1}y_2$ , for  $i = 0, \dots, 9$ , then the condition  $\tilde{f}(P) = \tilde{f}(Q) = 0$ , that is

$$\sum_{i=1}^{10} g_i(1, 0)h_i(0, 0, 1) = \sum_{i=1}^{10} g_i(0, 1)h_i(1, 0, 0) = 0$$

implies

$$\sum_{i=0}^9 v_{4i+2}v_{4i+1} = \sum_{i=0}^9 v_{4i+3}v_{4i} = 0.$$

Our aim is thus to find the set of  $\{v_0, \dots, v_{39}\} \in \mathbb{C}^{40}$  such that  $\tilde{f}$  expresses as

$$(6.3) \quad \tilde{f} = \sum_{i=0}^9 [(v_{4i+2}s + v_{4i+3}t)(y_0 + v_{4i}y_1 + v_{4i+1}y_2)^5 - v_{4i+2}v_{4i+1}sy_2^5 - v_{4i+3}v_{4i}ty_1^5],$$

where, in each summand, the monomials  $v_{4i+2}v_{4i+1}sy_2^5$ ,  $v_{4i+3}v_{4i}ty_1^5$  are subtracted so that  $\tilde{f}$  vanishes at  $P$  and  $Q$ . Equivalently, if  $[p_0, \dots, p_{39}]$  represents a set of homogeneous coordinates for  $\tilde{f}$ , then

$$(6.4) \quad \begin{pmatrix} p_0 & \dots & p_{14} & p_{15} & \dots & p_{19} & 0 \\ p_{20} & \dots & p_{34} & 0 & p_{35} & \dots & p_{39} \end{pmatrix} = \sum_{i=0}^9 \left[ \begin{pmatrix} v_{4i+2} \\ v_{4i+3} \end{pmatrix} \nu_5(1, v_{4i}, v_{4i+1}) - \begin{pmatrix} 0 & \dots & 0 & 0 & \dots & 0 & v_{4i+2}v_{4i+1} \\ 0 & \dots & 0 & v_{4i+3}v_{4i} & 0 & \dots & 0 \end{pmatrix} \right]$$

where  $\nu_5$  denotes the Veronese map of  $\mathbb{P}^2$  of degree 5. The equality of matrices appearing in (6.4) translates into a non linear system consisting, in principle, of 42 equations. It is immediate to see that the condition  $\tilde{f}(P) = \tilde{f}(Q) = 0$  implies that two equations, corresponding respectively to the monomials  $sy_2^5$  and  $ty_1^5$ , are trivial. Thus, we get a square non linear system with 40 equations, with  $\{v_0, \dots, v_{39}\}$  as unknowns. We focus on the system  $F_{(p_0, \dots, p_{39})}([v_0, \dots, v_3], \dots, [v_{36}, \dots, v_{39}])$  obtained from the one mentioned above by re-arranging all the terms in each equation on one side of the equal sign.

In practice, to work with a general  $\tilde{f}$ , we change  $\{v_0, \dots, v_{39}\}$  with random complex numbers  $\{\underline{v}_0, \dots, \underline{v}_{39}\}$  (*start-point*) and then we compute, by means of (6.4), the corresponding  $[\underline{p}_0, \dots, \underline{p}_{39}]$  (vector of *start-parameters*). By construction, the start-point is a solution of  $F_{(\underline{p}_0, \dots, \underline{p}_{39})}$ . In particular, the chosen start-point is the following:

$$\begin{aligned} [\underline{v}_0, \underline{v}_1, \underline{v}_2, \underline{v}_3] &= [3.803150504548735 \cdot 10^{-1} + i1.080968803617349 \cdot 10^{-1}, \\ &\quad 4.012914786260265 \cdot 10^{-2} + i1.194906105430308 \cdot 10^{-2}, \\ &\quad -5.791791173087690 \cdot 10^{-1} + i7.036742613968909 \cdot 10^{-1}, \\ &\quad -3.976968438023937 \cdot 10^{-1} + i9.044873244848521 \cdot 10^{-1}] \\ [\underline{v}_4, \underline{v}_5, \underline{v}_6, \underline{v}_7] &= [2.231698943133415 \cdot 10^{-1} + i6.687608922343052 \cdot 10^{-1}, \\ &\quad 6.002906583490685 \cdot 10^{-1} + i2.206993065311951 \cdot 10^{-1}, \\ &\quad 3.867065923659511 \cdot 10^{-1} + i1.345756657407951 \cdot 10^{-1}, \\ &\quad 1.526038777608076 \cdot 10^{-1} - i6.566938139632470 \cdot 10^{-1}] \\ [\underline{v}_8, \underline{v}_9, \underline{v}_{10}, \underline{v}_{11}] &= [-1.736311597636939 \cdot 10^{-1} - i7.609350872905872 \cdot 10^{-1}, \end{aligned}$$

$$\begin{aligned}

 \end{aligned}$$

At this point, by replacing in  $F_{(\underline{p}_0, \dots, \underline{p}_{39})}$  the start-parameters with random complex values, we get two square polynomial systems  $F_1, F_2$  of order 40 and then we construct 3 segment homotopies  $H_i : \mathbb{C}^{40} \times [0, 1] \rightarrow \mathbb{C}^{40}$  for  $i \in \{0, 1, 2\}$ , so that  $H_0$  is between  $F_{(\underline{p}_0, \dots, \underline{p}_{39})}$  and  $F_1$ ,  $H_1$  connects  $F_1$  with  $F_2$  and  $H_2$  closes the *triangle-loop*. By means of  $H_0$ , we have a *path* from the start-point to a solution of  $F_1$  (*endpoint*), which at the second step becomes a start-point for  $H_1$ , and so on. At the end of the triangle-loop, the output is compared with  $\{\underline{v}_0, \dots, \underline{v}_{39}\}$ . Since they differ, we restart the loop with these two as start-points, and so on. From the 6<sup>th</sup> iteration on, the number of solutions of  $F_{(\underline{p}_0, \dots, \underline{p}_{39})}$  stabilizes on 18:  $\{\underline{v}_0, \dots, \underline{v}_{39}\}$  plus other 17 points (we refer to the ancillary file <https://arxiv.org/src/1911.07769v2/anc/CatIntConf.pdf> for the complete list of points and to the ancillary folder `ternarie.4444` for all the files of which our procedure consists of). Therefore  $[\underline{p}_0, \dots, \underline{p}_{39}]$  has 18 decompositions, which allows us to conclude the proof.  $\square$

As a consequence of Corollary 6.3 and Proposition 6.4, we get the following:

**Theorem\* 6.5.** *The general polynomial vector  $f$  with  $(n, r; a_1, \dots, a_r) = (2, 4; 4, 4, 4, 4)$  admits 18 simultaneous Waring decompositions with 10 summands.*

**Remark\* 6.6.** Theorem 6.5 answers one of the open problems introduced in [4]. Indeed, thanks to Corollary 6.3, we focused on a square polynomial system of order 40 instead of the starting one of order 60, for which our computational technique did not provide an answer.

By arguing as in Remark 4.7, from Theorem 6.5 and the observation that the linear space of cubic forms in three variables has dimension 10, we deduce the following:

**Corollary\* 6.7.** *The general polynomial vector  $f = (f_1, f_2, f_3, f_4, \dots, f_r)$  with  $f_i \in \text{Sym}^4 \mathbb{C}^3$  for  $i \in \{1, 2, 3, 4\}$  and  $f_i \in \text{Sym}^3 \mathbb{C}^3$  for  $i \in \{5, \dots, r\}$  admits 18 simultaneous Waring decompositions with 10 summands.*

As we mentioned in the Introduction, we want to repeat here that computations by Bertini do not provide a theoretical proof that the number of decompositions is 18, but they give us a strong evidence of the result. This is the reason for the asterisk before the statement of the previous results.

**Remark 6.8.** There are indeed two reasons for which the previous computation do not provide a theoretically complete proof that the number of different decompositions of a polynomial vector of type  $(2, 4; 4, 4, 4, 4)$  is 18. First, the computation has been performed with a choice of specific vectors  $f$  which, in principle, could be all contained in the Zariski closed locus where the number of decompositions is not general. Second, even if the computation by Bertini stops after a certain lapse of time by returning 18 decomposition, there is no theoretical guarantee that we found all possible decompositions of  $f$ .

For the latter reason, there is nothing to do and we can only refer to the reliability of computations by Bertini, discussed in the paper [18].

On the other hand, for the former reason, we can argue that, by [4], the secant variety of the Segre-Veronese embedding of  $\mathbb{P}^2 \times \mathbb{P}^3$  of bi-degree  $(1, 4)$  is  $\mathbb{P}^{59}$ , which is a normal variety. Then the Zariski Main Theorem and the Stein Factorization Theorem ([17], p.280) prove that the number of connected components of the variety of the decompositions of a generic polynomial vector cannot be smaller than the number of connected components for a specific  $f$ . One can use [12], Lemma 2.5 in order to prove that the 18 decompositions of  $f$  that we found in Proposition\* 6.4 are isolated.

The previous remark implies that the following result (without asterisk) holds.

**Theorem 6.9.** *A general polynomial vector of type  $(2, 4; 4, 4, 4, 4)$  has at least 18 decompositions in terms of polynomial vector of rank 1.*

## 7. FINAL CONSIDERATIONS

**Remark 7.1.** After one realizes that catalecticant maps and confinement are useful to determine the number of simultaneous decompositions of 3 cubics or 4 quartics, one may imagine that the procedure extends to the study of simultaneous decompositions of  $d$  forms of degree  $d$  in 3 variables. Unfortunately, this does not happen. For example, the generic rank of 5 ternary forms of degree 5 is 15 ([4]). On the other hand, there are no catalecticant maps providing a confinement for the sets of 15 points that decompose a general vector of 5 quintics. For instance, derivatives of order 4 determine a map  $\mathbb{C}^{15} \rightarrow \mathbb{C}^{15}$  which is generically bijective and covers the whole space spanned by  $\mathbb{P}^2 \times \mathbb{P}^4$ .

We can analyze with catalecticant maps other types of polynomial vectors, if we consider the case in which the rank is not the generic one, and the decomposition is not unique.

**Example 7.2.** Let us assume that  $r = 1$ ,  $n = 2$ ,  $a_1 = 6$ , i.e. we deal with  $X_6^2 = \nu_6(\mathbb{P}^2) \subset \mathbb{P}^{27}$ , being  $\nu_6 : \mathbb{P}^2 \rightarrow \mathbb{P}^{27}$  the Veronese map of  $\mathbb{P}^2$  of degree 6. This case is not perfect, but nevertheless we focus on the generic  $f = f_1 \in \text{Sym}^6 \mathbb{C}^3$  having the first sub-generic rank, i.e.  $k = 9$ . This is a classical case. It is well known (see e.g. Theorem 1.1 of [13]) that such  $f$  has two Waring decompositions with 9 summands, because of the presence of an elliptic normal curve of degree 3 in  $\mathbb{P}^2$  passing through the 9 points of a decomposition of  $f$ . Indeed, the elliptic cubic maps, via the 6-Veronese embedding, to an elliptic normal curve in  $\mathbb{P}^{17}$  containing all the decompositions of  $f$ , which then are exactly 2 by Proposition 5.2 of [10].

We show how this example also follows from a catalecticant map. Consider the *catalecticant map* of the contraction by  $f$

$$C_f^3 : (\text{Sym}^3 \mathbb{C}^3)^\vee \rightarrow \text{Sym}^3 \mathbb{C}^3$$

where  $(\text{Sym}^3 \mathbb{C}^3)^\vee$  can be identified with the space of polynomial derivatives in 3 variables of order 3.  $C_f^3$  is associated to a square matrix of order 10, with 0-degree entries, denoted also by  $C_f^3$ , where in each column there are the components, with respect to the standard monomial basis of  $\mathbb{C}[x_0, x_1, x_2]_3$ , of  $\partial_{x_u} \partial_{x_v} \partial_{x_w} f$ , with  $u, v, w \in \{0, 1, 2\}$ . More in detail, assuming that  $f = \sum_{i=1}^9 \lambda_i \ell_i^6$ , where, for simplicity,  $\ell_i = x_0 + \mu_i^1 x_1 + \mu_i^2 x_2$ ,  $i \in \{1, \dots, 9\}$ , we get that  $C_f$  equals

$$120 \sum_{i=1}^9 \lambda_i (C_i | 3\mu_i^1 C_i | 3\mu_i^2 C_i | 3\mu_i^1 \mu_i^1 C_i | 6\mu_i^1 \mu_i^2 C_i | 3\mu_i^2 \mu_i^2 C_i | \mu_i^1 \mu_i^1 \mu_i^1 C_i | 3\mu_i^1 \mu_i^1 \mu_i^2 C_i | 3\mu_i^1 \mu_i^2 \mu_i^2 C_i | \mu_i^2 \mu_i^2 \mu_i^2 C_i)$$

where

$$C_i = (1, 3\mu_i^1, 3\mu_i^2, 3\mu_i^1 \mu_i^1, 6\mu_i^1 \mu_i^2, 3\mu_i^2 \mu_i^2, \mu_i^1 \mu_i^1 \mu_i^1, 3\mu_i^1 \mu_i^1 \mu_i^2, 3\mu_i^1 \mu_i^2 \mu_i^2, \mu_i^2 \mu_i^2 \mu_i^2)^t \in \nu_3([\ell_i^\vee])$$

being  $\nu_3 : \mathbb{P}^2 \rightarrow \mathbb{P}^9$  the Veronese map of  $\mathbb{P}^2$  of degree 3 and  $\ell_i^\vee = (1, \mu_i^1, \mu_i^2)$  a representative vector for the dual point of  $\ell_i$ . An explicit computation with Macaulay2 shows that for a generic choice of  $f$  we have that:

- $C_f^3$  has rank 9;
- $\mathcal{C}_9 = \mathbb{P}(\text{im}(C_f^3)) \cap X_3^2 \subset \mathbb{P}^8$  is an elliptic curve of degree 9;
- $\mathbb{P}(\text{im}(C_f^3)) = \langle \nu_3([\ell_1^\vee]), \dots, \nu_3([\ell_9^\vee]) \rangle$ .

For a computational verification of these properties, see the ancillary file <https://arxiv.org/src/1911.07769v2/anc/CatIntConf.pdf>. By semicontinuity, it suffices to prove the above properties for a random choice of the  $\ell_i$ 's. Therefore, for generic choice of  $f$  and for all  $i \in \{1, \dots, 9\}$ , the points  $\nu_3([\ell_i^\vee]) \in \mathcal{C}_9 = \nu_3(\mathcal{C}_3)$ , where  $\mathcal{C}_3 \subset \mathbb{P}^2$  is the unique elliptic normal curve of degree 3 passing through the points  $[\ell_i^\vee]$ , according to Theorem 1.1 of [13].

**Example 7.3.** Let us assume that  $r = 1$ ,  $n = 2$ ,  $a_1 = 8$ , i.e. we deal with  $X_8^2 = \nu_8(\mathbb{P}^2) \subset \mathbb{P}^{44}$ , being  $\nu_8 : \mathbb{P}^2 \rightarrow \mathbb{P}^{44}$  the Veronese map of degree 8. We focus on  $f \in \text{Sym}^8 \mathbb{C}^3$  having the first sub-generic rank, i.e.  $k = 14$ .

By [13], we know that the general  $f$  as above is identifiable, i.e. it has a unique decomposition as a sum of 14 powers of linear forms. Nevertheless, by Section 4 of [3] we know that in the span of 14 generic powers of linear forms there are forms  $g$  which have two decompositions, the second decomposition formed by linear forms different from the original ones.

By the analysis carried on in [3], it turns out that for a general choice of 14 linear forms  $L_i$  in 3 variables (which can be identified as general points in a space  $\mathbb{P}^2$ ), the second decompositions of

forms  $g$  in the span of the set  $\{L_1^8, \dots, L_{14}^8\}$  are determined by linear forms  $M_1, \dots, M_{14}$  which lie in the unique quartic curve  $C$  in  $\mathbb{P}^2$  which passes through  $L_1, \dots, L_{14}$ .

This is a case of confinement of the possible second decompositions of forms generated by  $\{L_1^8, \dots, L_{14}^8\}$ , which is confirmed by a catalecticant analysis. Namely, the image of the fourth-order derivatives of  $f$  span a hyperplane in the space  $\mathbb{P}^{14} = \mathbb{P}(\text{Sym}^4 \mathbb{C}^3)$ , which meets the image of  $\mathbb{P}^2$  in the 4th Veronese map  $\nu_4$  in a curve: the curve is exactly  $\nu_4(C)$ .

Notice that one cannot use the catalecticant map to decide whether or not a form  $f$  as above is identifiable. When the image of the catalecticant map has the correct dimension, then it only depends on the linear forms  $L_i$ 's. Thus, the existence of forms like  $g$  in the span of  $L_1^8, \dots, L_{14}^8$ , whose second decompositions cover  $C$ , forces the image of the catalecticant map to intersect the Veronese surface  $\nu_4(\mathbb{P}^2)$  in a curve, and not in a finite set.

Catalecticant maps can guarantee the identifiability of a specific form  $f$  only when the span of a minimal decomposition  $A = \{L_1, \dots, L_k\}$  of  $f$  only contains forms whose unique minimal decomposition is a subset of  $A$ .

**Remark 7.4.** A result by Ballico ([5], Thm.1.2), in the spirit of the two previous examples, provides other cases of confinement of decompositions. Ballico essentially proves that if a decomposition  $A$  of a form  $f$  poses independent conditions to forms of degree  $d' = \lfloor d/2 \rfloor$ , then any other decomposition  $B$  of  $f$  with cardinality smaller or equal than  $A$  must lie in the set  $X$  cut by forms of degree  $d'$  passing through  $A$ . When  $X$  is positive dimensional, then it is possible that  $f$  has many different decompositions, all of them confined to  $X$ . An example of application of this confinement result, for quartics of rank 12 in 5 variables, will be the subject of a forthcoming paper.

Corollary 4.6 and Corollary 6.7 are a consequence of a more general observation.

**Remark 7.5.** Let  $f = (f_1, \dots, f_r)$  be a general polynomial vector of rank  $k$  over  $\mathbb{F}$ , such that  $f_j \in \mathbb{F}[x_0, \dots, x_n]_{a_j}$ . Let  $f_{r+1}, \dots, f_s$  be general elements of  $\mathbb{F}[x_0, \dots, x_n]_{a_{r+1}}$ , with  $a_{r+1} \leq a_r$ . If  $k \geq \binom{a_{r+1}+n}{a_{r+1}}$ , then the number of simultaneous Waring decompositions of  $f' = (f_1, \dots, f_s)$  with  $k$  summands is greater or equal than the one of  $f$ , unless a defective case occurs.

Instances of this phenomenon are  $(n, r; a_1, \dots, a_r) = (2, 3; 3, 3, 3)$  with  $k = 6$  (as stated in Corollary 4.6, by adding to a triple of ternary cubics an arbitrary number of conics, the decompositions with six summands of the corresponding multiform are still two), and  $(n, r; a_1, \dots, a_r) = (2, 4; 4, 4, 4, 4)$  with  $k = 10$  (as stated in Corollary 6.7, by adding to four ternary quartics an arbitrary number of cubics, the decompositions with ten summands of the corresponding multiform are still 18).

**Remark 7.6.** Another perfect case in which the catalecticant approach gives a confinement of the decompositions is  $(n, r; a_1, \dots, a_r) = (3, 3; 3, 3, 3)$ , with  $k = 10$ . In this situation the decompositions are confined to a general threefold section of  $\mathbb{P}^2 \times \mathbb{P}^3$ . The section is again birational to  $\mathbb{P}^2 \times \mathbb{P}^1$ , but the map is defined by divisors of type  $(4, 3)$ , with two general triple points, so it is different and more complicated than the one of Corollary 5.2.

The number of simultaneous decomposition of 3 quaternary cubics is 56. It has been determined, by Bertini, in the paper [4].

**Remark 7.7.** Let  $f = (f_1, \dots, f_r)$  be a general polynomial vector such that  $f_j \in \mathbb{F}[x_0, \dots, x_n]_{a_1}$  for any  $j$ . The rank of  $f$  over  $\mathbb{F}$  is  $k = \left\lceil \frac{r}{n+r} \binom{a_1+n}{n} \right\rceil$ ; see [4]. Let  $f_{r+1}, \dots, f_{r+s}$  be general elements of  $\mathbb{F}[x_0, \dots, x_n]_{a_2}$ , with  $a_2 < a_1$ . The rank over  $\mathbb{F}$  of the multiform  $f' = (f_1, \dots, f_{r+s})$  is given by  $k' = \left\lceil \frac{1}{n+r+s} (r \binom{a_1+n}{n} + s \binom{a_2+n}{n}) \right\rceil$ , [4]. If  $k \geq k'$ , then  $X_{a_1, \dots, a_1, a_2, \dots, a_2}^n$ , where  $a_1$  and  $a_2$  are

repeated, respectively,  $r$  and  $s$  times, is  $k'$ -defective. For example, this fact occurs in the following cases:

- $(n, r; a_1) = (2, 1; 8)$ , with  $k = 15, s = 1, a_2 = 4, k' = 15$ ;
- $(n, r; a_1) = (2, 1; 12)$ , with  $k = 31, s = 1, a_2 = 5, k' = 28$ ;
- $(n, r; a_1) = (2, 1; 19)$ , with  $k = 70, s = 1, a_2 = 3, k' = 55$ .

Let us finally notice that the case addressed in Theorem 4.4 is quite peculiar. One can numerically show that there are no other pairs of projective bundles  $X_{d,\dots,d}^n$  and  $X_{d,\dots,d,d-1}^n$ , with  $n \geq 2$  and  $d \geq 3$ , providing two perfect cases with the same rank  $k$  and  $\dim(X_{1,\dots,1}^n \cap \mathbb{P}^{k-1}) = 1$  (in the three projective bundles quoted above, the dots denote that the same degree -  $d$  or  $1$  - is repeated  $r - 1$  times).
