Motivation and Goals

- Quantum resources (states, measurements, channels, ...) provide advantages that can be operationally quantified
- Quantifying a given resource typically requires well characterised states and/or measurements to probe the resource
- What resources can be characterised in a device independent way?
- **Goal:** use techniques from self-testing to certify and quantify any resourceful object in a black-box setting

Quantum Resources

We consider resources with convex free sets:

- **States:** entanglement, steerability, non-Gaussianity, magic, ...
- **Measurements:** incompatibility, non-projective-simulability, ...
- **Channels:** non-entanglement-breaking and non-incompatibility-breaking channels, thermal operations, ...

We focus on channel resources

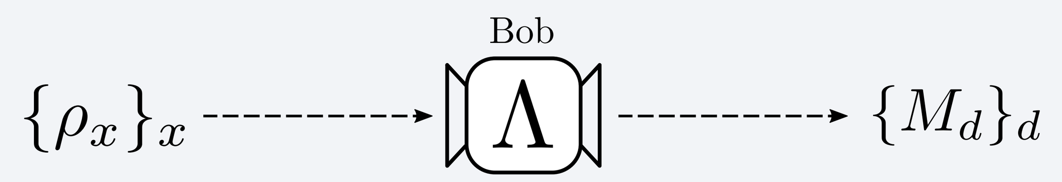
- The resourcefulness of Λ w.r.t. a free set F can be quantified with the generalised robustness:

$$R_F(\Lambda) = \min_{\tilde{\Lambda}} \left\{ t \geq 0 \,\middle|\, \frac{\Lambda + t\tilde{\Lambda}}{1+t} \in F \right\}$$

Resource Quantification with Input-Output Games [2]

- $R_F(\Lambda)$ related to operational advantage in an input-output game $\mathcal{G} = (\mathcal{E}, \mathcal{M}, \Omega)$:

$$\begin{aligned} \mathcal{E} &= \{p(x)\rho_x\}_x && \text{(input state ensemble)} \\ \mathcal{M} &= \{M_d\}_d && \text{(a POVM)} \\ \Omega &= \{w_{x,d}\}_{x,d} && \text{(score)} \end{aligned}$$



$$P(\Lambda, \mathcal{G}) = \sum_{x,d} p(x)\, \omega_{x,d}\, \mathrm{tr}[\Lambda(\rho_x) M_d] \qquad \text{(payout)}$$

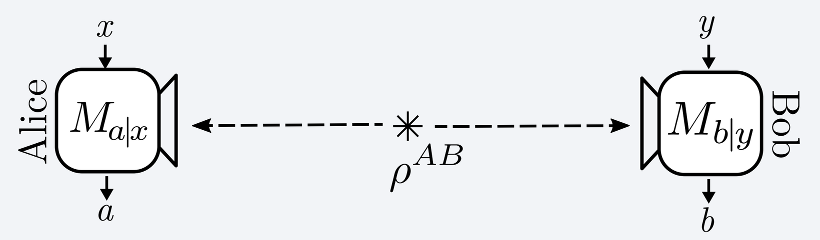
- For well-normalised input-output games, payout a resource can give is directly related to its robustness:

$$1 + \mathcal{R}_F(\Lambda) = \max_{\mathcal{G}} P(\Lambda, \mathcal{G})$$

- Device dependent: Must trust $\mathcal{E}$ and $\mathcal{M}$!

Self-testing [3]

Certify exact form of a state and measurements from correlations $p(a,b|x,y)$

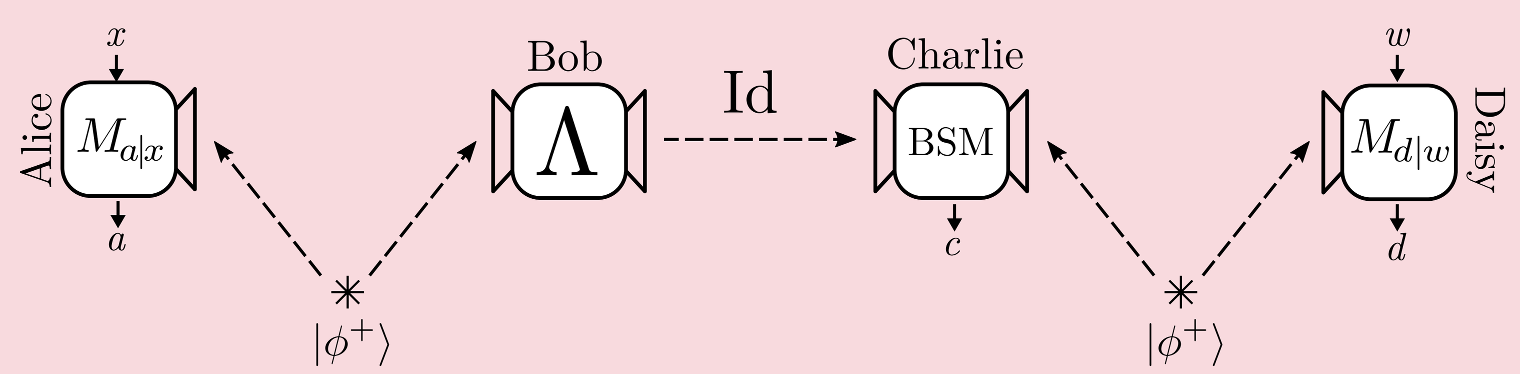


- E.g.: maximal violation of a Bell inequality can certify:
  - $\rho \simeq |\phi^+\rangle\langle\phi^+|$, Alice and Bob measure Pauli X, Y, Z
- Certification up to local isometries and complex conjugate

Reference Scenario & Protocol

Use self-testing to characterise, device-independently:

- remote preparation of pure states states $\{\rho_x\}_x$
- arbitrary measurement $\{M_d\}_d$



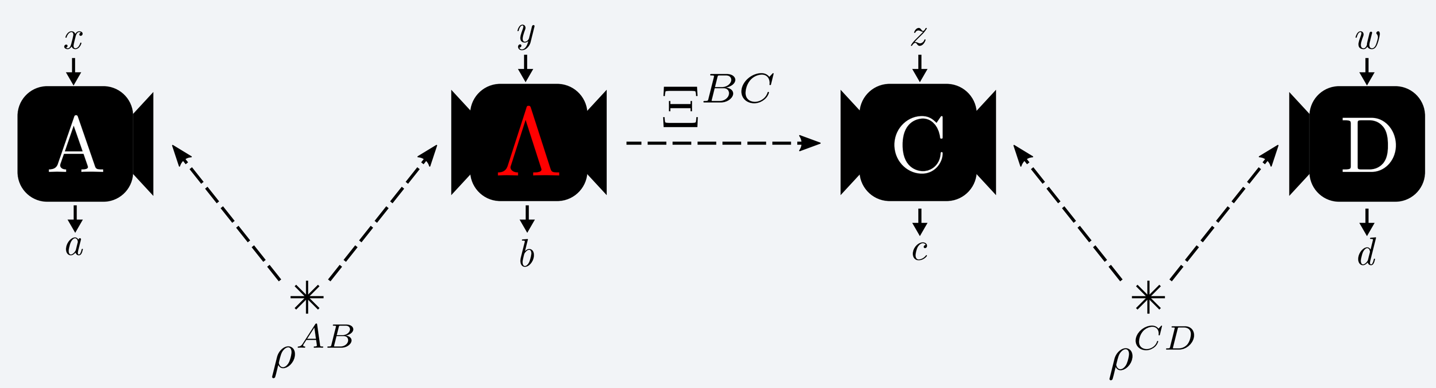
1. On input x, Alice remotely prepares ρ_x for Bob by performing a suitable measurement on her share of $|\phi^+\rangle^{AB}$.
2. Bob applies Λ to ρ_x and sends $\Lambda(\rho_x)$ to Charlie via the identity channel Id.
3. Charlie performs a Bell-state measurement (BSM) on $\Lambda(\rho_x)$ and his share of $|\phi^+\rangle^{CD}$, teleporting to Daisy the state $\sigma_c \Lambda(\rho_x) \sigma_c^\dagger$.
4. Daisy measures $\{M_{d|w}\}_d = \{\sigma_w M_d \sigma_w^\dagger\}_d$ on the teleported state; for $w = c$ this is equivalent to measuring $\{M_d\}_d$ on $\Lambda(\rho_x)$.

$$P(\Lambda, \mathcal{G}) = \sum_{x,d} p(x)\, \omega_{x,d} \sum_{c,w} \frac{1}{p(0|x)} p(0,c,d|x,w)\, \delta_{c,w}$$

Device-independent Quantification Protocol

Add extra inputs to self-test (up to local isometries):

- Maximally entangled states ρ^{AB} and ρ^{CD}
- Pauli X, Y, Z measurements for Alice and Daisy
- Identity channel Ξ^{BC}
- Bell-state measurement for Charlie



Quantification Statement

- The statistics on "quantification rounds" give the payoff $P(\Lambda^{\text{ext}}, \mathcal{G})$ of an effective (extractable) channel

$$\Lambda^{\text{ext}} = h_{00}\Lambda_{00}^{\text{ext}} + h_{11}\tilde{\Lambda}_{11}^{\text{ext}}$$

  - $\tilde{\Lambda}_{11}^{\text{ext}}(\rho) = \Lambda_{11}^{\text{ext}}(\rho^*)^*$ (conjugate channel)
  - $\Lambda_{ii}^{\text{ext}}$ can be extracted with local isometries from the physical effective channel $\mathcal{T}^{C\to D} \circ \Xi^{BC} \circ \Lambda$ from Bob to Daisy and takes into account "junk states" ξ_{ii} arising during extraction
  - Λ_{00} and Λ_{11} differ in junk states arising from self-testing (indistinguishability of correlated Alice-Daisy conjugation)
- DI certification that we can extract a channel with payout $P(\Lambda^{\text{ext}}, \mathcal{G})$ on $\mathcal{G}$

Relation to Physical Channel

For "well-behaved" resources:

- **Resource certification:** If Λ is resourceless, so is Λ^{ext}
- **Quantification bound:** $P(\Lambda^{\text{ext}}, \mathcal{G}) \leq \max_{\mathcal{G}'} P(\Lambda, \mathcal{G}')$
  - i.e., $R_F(\Lambda^{\text{ext}}) \leq R_F(\Lambda)$

Resource must satisfy certain preconditions:

- Can't be increased by local unitaries
- Insensitive to channel conjugation
- Unaffected by attaching extra DOFs that measurements are trivial on

Examples

- Non-entanglement-breaking and non-incompatibility-breaking channels are faithfully quantified in this way
- Can be significantly simplified for state or measurement resources
  - E.g., input-output games $\rightarrow$ state-discrimination games
  - Complements known DI certification of all entangled states [4]
- We likewise obtain a fully black-box certification of any sets of incompatible measurements

Conclusions and Open Questions

- DI certification of any* resourceful channel
- Correlations quantify the resourcefulness of implemented channel
- Causal network structure of protocol important to its success
- Full characterisation of which resources can be quantified in this way?
