Abstract: In this paper, we study linear control systems over Ore algebras. Within this mathematical framework, we can simultaneously deal with different classes of linear control systems such as time-varying systems of ordinary differential equations (ODEs), differential time-delay systems, underdetermined systems of partial differential equations (PDEs), multidimensional discrete systems, multidimensional convolutional codes etc. We give effective algorithms which check whether or not a linear control system over some Ore algebra is controllable, parametrizable, flat or π -free.

Key-words: Linear systems over Ore algebras, controllability, parametrization, flatness, π -freeness, effective algorithms, non-commutative Gröbner bases.

Algorithmes effectifs pour la paramétrisation des systèmes de contrôle linéaires sur des algèbres de Ore

Résumé : Dans ce papier, nous étudions les systèmes de contrôle linéaires sur des algèbres de Ore. Cette approche nous permet d'étudier dans un même cadre mathématique différentes classes de systèmes de contrôle linéaires telles que les systèmes d'équations différentielles ordinaires (EDOs) variants dans le temps, les systèmes différentiels à retards, les systèmes sous-déterminés d'équations aux dérivées partielles (EDPs), les systèmes multidimensionnels discrets, les codes convolutionnels multidimensionnels etc. Nous donnons des algorithmes effectifs vérifiant si un système de contrôle linéaire sur une algèbre de Ore est contrôlable, paramétrisable, plat ou π -libre.

Mots-clés : Systèmes linéaires sur des algèbres de Ore, contrôlabilité, paramétrisation, platitude, π -liberté, algorithmes effectifs, bases de Gröbner non-commutatives.

1 Introduction

Over the last thirty years, for practical and theoretical reasons, different new classes of linear control systems have been introduced such as differential time-delay systems, multidimensional systems, partial differential equations, convolutional codes, hybrid systems... All these classes of systems are governed by new types of mathematical equations and have needed new techniques in order to analyze their structural properties and to synthesize new control laws. This growth of new types of control systems has led to generalize some previously known results and techniques so that they could be used for more general classes of systems. The main interest is to get similar concepts, techniques and algorithms for studying different classes of linear systems.

In this paper, we study linear control systems over *Ore algebras*. An Ore algebra is an algebra of non-commutative functional operators which satisfy certain commutation rules. For instance, differential/time-delay/advance/discrete shift/divided difference... operators are examples of elements of some Ore algebras. Within this mathematical framework, we can simultaneously deal with different classes of linear control systems such as time-varying ordinary differential systems (ODEs), differential time-delay systems, partial differential equations (PDEs), multidimensional discrete systems... Moreover, the recent extension of *Gröbner bases* to some non-commutative polynomial rings allows us to work effectively in Ore algebras [6, 7].

The purpose of this paper is to give effective algorithms which check whether or not a linear control system over some Ore algebra is controllable, parametrizable, flat or π -free. These problems have been intensively studied in [11, 20, 21] for linear differential time-delay systems and, in [22, 24, 25, 26, 27, 29, 30, 31, 32, 36, 37], for linear multidimensional systems. The main novelty of this paper is to present algorithms which work for both classes of systems as well as for new ones. In particular, our approach allows us to effectively obtain parametrizations of a controllable plant and flat outputs of a flat system. Let us notice that such algorithms were still missing for linear differential time-delay systems (see [11, 20, 21] for more details). The results developed in this paper give new effective machinery for the study of the structural properties of linear systems. We hope that they could play important roles for the study of motion planning or tracking [11, 20, 21].

Ore algebras are rings of non-commutative polynomials that represent linear functional operators in a natural way. A recent extension of the theory of Gröbner bases to this setting [5] makes manipulations of (one-sided) ideals of Ore algebras effective. We recall the basics of this theory in Section 2. As is the case for linear differential systems of algebraic analysis, a fundamental remark is that a module over an Ore algebra is canonically associated with any linear control system. Before we provide the readers in Section 4 with a dictionary, first introduced in [30], between structural properties of control systems and algebraic properties of modules, we recall in Section 3 the definitions and results of module theory to be used in the rest of the article. Next, the question is to algorithmically decide the algebraic properties of modules. This is done by means of homological algebra in Sections 5 and 7. The good point is that the central homological objects as syzygy modules, free resolutions, and extension modules can all be computed by algorithms which we recall and exemplify on cases of application. In passing, the classical notion of involution, which exchanges left and right module structures, is recalled in Section 6, where explicit examples of involutions of Ore algebras that appear in control theory are also given.

Beside realizing the applicability of non-commutative Gröbner bases to make the theory algorithmic, the main contribution of the paper lies in the new approach for the proofs of algorithms in Sections 8 and 9. These sections extend earlier results, previously obtained in special situations only, to the broad setting of linear control systems over Ore algebras. After collecting further results of homological algebra that could prove difficult to find in the literature, Section 8 gives an algorithm to determine whether a control system is parametrizable and, if so, to compute a parametrization, while, if not, to compute a basis of autonomous elements. Section 9 restricts to control systems over commutative Ore algebras in order to provide algorithms for deciding flatness, for studying π -freeness, and when they exist, for computing left and right inverses and minimal parametrizations.

In an appendix, we have illustrated all the main results and algorithms of the paper with explicit examples. All the computations were done using the Maple package *OreModules* written by the authors based on the library *Mgfun* [6]. These libraries as well as all the example worksheets of the appendix are available on the web page <http://wwwb.math.rwth-aachen.de/OreModules>. Some results are new (e.g., the parametrization of the electric transmission line [20, 34]) and we believe that these examples have some educational interest.

Some of the results developed in this paper were firstly presented in the conference papers [8, 9].

2 Ore algebras

2.1 Definition and examples

In order to deal with different classes of linear systems (ODEs, PDEs, differential time-delay systems, discrete systems, multidimensional systems...) in a unified framework, we represent them by means of matrices with entries in an *Ore algebra* of functional operators.

Definition 2.1. 1. [17] Let A be an integral domain (i.e., $ab = 0, a \neq 0 \Rightarrow b = 0$). The *skew polynomial ring* $A[\partial; \sigma, \delta]$ is the non-commutative ring consisting of all polynomials in ∂ with coefficients in A obeying the commutation rule

$$\partial a = \sigma(a) \partial + \delta(a), \quad a \in A, \quad (1)$$

where σ is a k -algebra endomorphism of A , namely $\sigma : A \rightarrow A$ satisfies

$$\begin{cases} \sigma(1) = 1, \\ \sigma(a + b) = \sigma(a) + \sigma(b), \quad a, b \in A, \\ \sigma(ab) = \sigma(a) \sigma(b), \quad a, b \in A, \end{cases}$$

and δ is a σ -derivation of A , namely $\delta : A \rightarrow A$ satisfies:

$$\begin{cases} \delta(a + b) = \delta(a) + \delta(b), \quad a, b \in A, \\ \delta(ab) = \sigma(a) \delta(b) + \delta(a) b, \quad a, b \in A. \end{cases}$$

2. [7] Let $A = k[x_1, \dots, x_n]$ be a commutative polynomial ring over a field k (if $n = 0$ then $A = k$). The iterated skew polynomial ring $D = A[\partial_1; \sigma_1, \delta_1] \dots [\partial_m; \sigma_m, \delta_m]$ is called *Ore algebra* if the σ_i 's and δ_j 's commute for $1 \leq i, j \leq m$ and satisfy:

$$\sigma_i(\partial_j) = \partial_j, \quad \delta_i(\partial_j) = 0, \quad j < i.$$

Remark 2.2. [7, 17] Let $D = A[\partial; \sigma, \delta]$ be a skew polynomial ring. Every element P of D has a unique normal form which is given by $P = \sum_{i=1}^n a_i \partial^i$ for suitable $a_i \in A$ and $n \in \mathbb{Z}_{\geq 0}$. If $a_n \neq 0$, then the degree of P is n . For every Ore algebra, we get a similar normal form of its elements by moving all products of $\partial_1, \dots, \partial_m$ on the right in each summand.

Example 2.3. Our first example is the Weyl algebra $A_1 = k[t][\partial; \sigma, \delta]$, where:

$$\sigma = \text{id}_{k[t]}, \quad \delta = \frac{d}{dt}.$$

Rule (1) expresses the commutation of the operator which acts as differentiation w.r.t. t :

$$\partial a = a \partial + \frac{da}{dt}, \quad a \in k[t], \quad \text{to compare with} \quad \partial(a y) = a \partial y + \left(\frac{da}{dt} \right) y.$$

For instance, we associate $R = [\partial I - A(t) : -B(t)] \in A_1^{n \times (n+m)}$ with the time-varying Kalman system $\dot{x}(t) = A(t) x(t) + B(t) u(t)$, where A and B are polynomial matrices in t .

Similar to polynomial rings in $2n$ indeterminates, we can define the so-called Weyl algebra $A_n = k[x_1, \dots, x_n][\partial_1; \sigma_1, \delta_1] \dots [\partial_n; \sigma_n, \delta_n]$, where σ_i and δ_i on $k[x_1, \dots, x_n]$ are the maps

$$\sigma_i = \text{id}_{k[x_1, \dots, x_n]}, \quad \delta_i = \frac{\partial}{\partial x_i}, \quad i = 1, \dots, n,$$

and every other commutation rule is prescribed by Definition 2.1. In particular, we have:

$$\partial_i x_j = x_j \partial_i + \delta_{ij}, \quad 1 \leq i, j \leq n, \quad \text{where } \delta_{ij} = 1, \text{ if } i = j, \text{ and } 0 \text{ else.}$$

Example 2.4. The algebra of shift operators with polynomial coefficients is another special case of an Ore algebra. For $h \in \mathbb{R}$, we define $S_h = k[t][\delta_h; \sigma_h, \delta]$ by:

$$\sigma_h(a)(t) = a(t - h), \quad \delta(a) = 0, \quad a \in k[t].$$

Hence, the commutation rule $\delta_h t = (t - h) \delta_h$ actually represents the action of the shift operator on polynomials. For instance, the matrix of operators $R = [1 - \delta_h : -\delta_h^2] \in S_h^{1 \times 2}$ is associated with the time-delay system $x(t) = x(t - h) + u(t - 2h)$. Let us notice that ∂_h is a *time-delay operator* if $h > 0$ and an *advance operator* if $h < 0$.

Example 2.5. In order to treat differential time-delay systems, we mix the constructions of the two preceding examples. We define the Ore algebra $D_h = k[t][\partial; \sigma_1, \delta_1][\delta_h; \sigma_2, \delta_2]$, where:

$$\sigma_1 = \text{id}_{k[t]}, \quad \delta_1 = \frac{d}{dt}, \quad \sigma_2(a)(t) = a(t-h), \quad \delta_2 = 0, \quad h \in \mathbb{R}, \quad a \in k[t].$$

For instance, we associate the matrix $R = [\partial I - A(t) : -B(t) \delta_h] \in D_h^{n \times (n+m)}$ with the system $\dot{x}(t) = A(t)x(t) + B(t)u(t-h)$, where A and B are polynomial matrices in t .

If the considered system also involves the advance operator, which is the inverse operator of the time-delay operator, then we may work with the Ore algebra

$$H_h = k[t][\partial; \sigma_1, \delta_1][\delta_h; \sigma_2, \delta_2][\tau_h; \sigma_3, \delta_3],$$

where $\sigma_i, \delta_i, i = 1, 2$, are as above and:

$$\sigma_3(a)(t) = a(t+h), \quad \delta_3 = 0, \quad a \in k[t].$$

We then compute with elements of H_h modulo $\delta_h \tau_h = \tau_h \delta_h = 1$.

Example 2.6. In order to study multidimensional discrete linear systems, we define the following Ore algebra $D = k[x_1, \dots, x_n][\partial_1; \sigma_1, \delta_1] \dots [\partial_n; \sigma_n, \delta_n]$, where σ_i and δ_i on $k[x_1, \dots, x_n]$ are the maps:

$$\sigma_i(a)(x_1, \dots, x_n) = a(x_1, \dots, x_{i-1}, x_i + 1, x_{i+1}, \dots, x_n), \quad \delta_i = 0, \quad i = 1, \dots, n.$$

Similarly to Example 2.5, we can define an Ore algebra which combines the shift operator σ_i and the inverse shift τ_i defined by $\tau_i(a)(x_1, \dots, x_n) = a(x_1, \dots, x_{i-1}, x_i - 1, x_{i+1}, \dots, x_n)$. Such a construction is then a generalization of the Laurent polynomial ring to non-commutative polynomials.

Ore algebras based on other functional operators can also be defined (discrete shifts, divided differences, q -shift, Eulerian operators...). We refer to [7, 17] for more examples.

2.2 Properties of Ore algebras & Gröbner bases

We summarize the most important properties of Ore algebras that will enable us to computationally deal with modules over Ore algebras.

Proposition 2.7. [7] *If A has the left Ore property (resp. right Ore property), namely, for each pair $(a_1, a_2) \in A \times A$, there is a pair $(0, 0) \neq (b_1, b_2) \in A \times A$ such that $b_1 a_1 = b_2 a_2$ (resp. $a_1 b_1 = a_2 b_2$), then $A[\partial; \sigma, \delta]$ has also the left (resp. right) Ore property.*

Proposition 2.8. [17] *If A is an integral domain and σ is injective, then the skew polynomial ring $A[\partial; \sigma, \delta]$ is an integral domain.*

Proposition 2.9. [17] *If A is a left noetherian ring and σ is an automorphism (e.g., A_n, S_h, D_h, H_h), then the skew polynomial ring $A[\partial; \sigma, \delta]$ is a left noetherian ring.*

In order to study systems over (non-commutative) polynomial rings effectively, we need to introduce some algorithmic methods based on Gröbner bases. We first need monomial orders to compare (non-commutative) polynomials.

Definition 2.10. 1. Let D be an Ore algebra. A *monomial order* $<$ on D is defined as a total order on the set of monomials $\text{Mon}(D)$ satisfying $1 < m$ for all monomials $m \in \text{Mon}(D)$ and, if $m_1 < m_2$ holds for two monomials $m_1, m_2 \in \text{Mon}(D)$, then $m_1 \cdot n < m_2 \cdot n$ for all $n \in \text{Mon}(D)$.

2. Given a polynomial $P \in D$ and a monomial order $<$, we can compare the monomials with a non-zero coefficient in P w.r.t. $<$. The greatest of these monomials is the *leading monomial* $\text{lm}(P)$ of P .

Definition 2.11. [1] Let A be a polynomial ring and I an ideal of A . A set of non-zero polynomials $G = \{g_1, \dots, g_t\}$ is called a *Gröbner basis* for I if for all $0 \neq f \in I$, there exists $1 \leq i \leq t$ such that $\text{lm}(g_i)$ divides $\text{lm}(f)$.

Remark 2.12. A consequence of the condition that defines Gröbner bases is that every polynomial f in I is *reduced* to 0 modulo G , i.e., by iterative division of f by suitable $g_i \in G$ we obtain the zero polynomial.

For the case of commutative polynomial rings, Buchberger's algorithm ([1, 2]) computes Gröbner bases of polynomial ideals. The next theorem states that this algorithm can be extended to certain Ore algebras. Every Ore algebra within our scope is of this kind.

Theorem 2.13. [7, 12] *Let $A = k[x_1, \dots, x_n]$ be the polynomial ring with n indeterminates over the field k and $A[\partial_1; \sigma_1, \delta_1] \dots [\partial_m; \sigma_m, \delta_m]$ an Ore algebra with*

$$\sigma_i(x_j) = a_{ij} x_j + b_{ij}, \quad \delta_i(x_j) = c_{ij} \quad 1 \leq i \leq m, \quad 1 \leq j \leq n, \quad (2)$$

for certain $a_{ij} \in k \setminus \{0\}$, $b_{ij} \in k$, $c_{ij} \in A$. If the c_{ij} are of total degree at most 1 in the x_i 's, then a non-commutative version of Buchberger's algorithm terminates for any monomial order on x_1, \dots, x_n , $\partial_1, \dots, \partial_m$, and its result is a Gröbner basis w.r.t. the given monomial order.

An important technique that uses Gröbner bases is *elimination of variables*.

Definition 2.14. [1] Let D be the polynomial ring over k with variables $x_1, \dots, x_n, y_1, \dots, y_m$. Assume that monomial orders $<_x$ and $<_y$ on the monomials that contain only the x_i 's or y_i 's resp. are given. An *elimination order* is then defined by

$$m_1 \cdot n_1 < m_2 \cdot n_2 \iff m_1 <_x m_2 \quad \text{or} \quad m_1 = m_2 \text{ and } n_1 <_y n_2,$$

where m_1, m_2 (resp. n_1, n_2) are monomials containing only the x_i 's (resp. y_i 's).

The elimination order which we shall use in this paper is the one induced by the degree reverse lexicographical orders on x_1, \dots, x_n and y_1, \dots, y_m resp.. This is a very common order called *lexdeg* in the Maple package *Groebner*.

Example 2.15. Given an ideal I of D , we obtain a Gröbner basis of the ideal $I \cap k[y_1, \dots, y_m]$ by computing the Gröbner basis G of I w.r.t. an elimination order and intersecting G with $k[y_1, \dots, y_m]$ (which amounts only to omit all polynomials in G that involve any x_i).

3 Module theory over Ore algebras

Let us give a motivation for the use of modules. Let D be an integral domain and let us consider a system of equations

$$\sum_{j=1}^p R_{ij} y_j = 0, \quad 1 \leq i \leq q, \quad (3)$$

where $R_{ij} \in D$, $p, q \in \mathbb{N}$. By collecting the coefficients R_{ij} , we obtain a matrix $R \in D^{q \times p}$ which, multiplied by the column vector $y = (y_1 : \dots : y_p)^T$, yields system (3) again.

Let us consider the following left D -morphism (D -linear map):

$$\begin{array}{ccc} D^{1 \times q} & \xrightarrow{.R} & D^{1 \times p}, \\ (P_1 : \dots : P_q) & \longmapsto & (P_1 : \dots : P_q) R. \end{array}$$

Then, $\text{im } .R = D^{1 \times q} R$ is the left D -module generated by the left D -linear combinations of the rows of R (namely, the ring D acts on the elements of $\text{im } .R = D^{1 \times q} R$ from the left).

Let us show how system (3) corresponds to the left D -module $M = D^{1 \times p} / D^{1 \times q} R$. We denote by $\{e_i\}_{1 \leq i \leq p}$ (resp. $\{f_j\}_{1 \leq j \leq q}$) the canonical basis of $D^{1 \times p}$ (resp. $D^{1 \times q}$), namely e_i is the row vector with 1 in i th position and 0 elsewhere. Let us define by $\pi : D^{1 \times p} \rightarrow M$ the left D -morphism which maps every element of $D^{1 \times p}$ to its residue class in M , i.e., modulo $D^{1 \times q} R$ ($\pi(\lambda_1) = \pi(\lambda_2) \iff \exists \mu \in D^{1 \times q}$ such that $\lambda_1 - \lambda_2 = \mu R$). Then, for $i = 1, \dots, p$, we have

$$f_j R = (R_{j1} : \dots : R_{jp}) = \sum_{i=1}^p R_{ji} e_i \in D^{1 \times q} R \Rightarrow \pi(f_j R) = \pi\left(\sum_{i=1}^p R_{ji} e_i\right) = \sum_{i=1}^p R_{ji} \pi(e_i) = 0,$$

and thus, if we denote by $y_i = \pi(e_i)$ the residue class of e_i in M , then M is defined by

$$\sum_{i=1}^p R_{ji} y_i = 0, \quad 1 \leq j \leq q, \quad \Leftrightarrow \quad R y = 0,$$

as well as by the left D -linear combinations of its equations, where $y = (y_1 : \dots : y_p)^T$. The left D -module $M = D^{1 \times p} / D^{1 \times q} R$ is *finitely generated* because every element $m \in M$ can be written as $m = \sum_{i=1}^p P_i y_i$, where $P_i \in D$.

Definition 3.1. We say that the finitely generated left D -module $M = D^{1 \times p} / D^{1 \times q} R$ is *associated with* (or *corresponds to*) (3).

Let us recall that if D is a commutative ring, then a left D -module M is also a right D -module and conversely. In this case, we shall only say that M is a D -module.

Example 3.2. Let us consider an Ore algebra $D_h = \mathbb{R}(a, k, \zeta, \omega)[\partial; \sigma_1, \delta_1][\delta_h; \sigma_2, \delta_2]$ of the type of Example 2.5 and revisit the following wind tunnel model defined in [19]

$$\begin{cases} \dot{x}_1(t) = -a x_1(t) + k a x_2(t - h), \\ \dot{x}_2(t) = x_3(t), \\ \dot{x}_3(t) = -\omega^2 x_2(t) - 2 \zeta \omega x_3(t) + \omega^2 u(t), \end{cases} \quad (4)$$

where a, k, ζ and ω are real constants. System (4) gives rise to the following matrix

$$R = \begin{pmatrix} \partial + a & -k a \delta_h & 0 & 0 \\ 0 & \partial & -1 & 0 \\ 0 & \omega^2 & \partial + 2 \zeta \omega & -\omega^2 \end{pmatrix} \in D_h^{3 \times 4}, \quad (5)$$

and thus, system (4) corresponds to the (left) D_h -module $M = D_h^{1 \times 4} / D_h^{1 \times 3} R$.

In Section 4, we shall develop a dictionary between the properties of the left D -module M and the properties of the system $Ry = 0$. But, at first, let us introduce some definitions of module theory and homological algebra.

Definition 3.3. [33] Let D be an integral domain.

1. A family $(M_i)_{i \in \mathbb{Z}}$ of D -modules together with a family $(d_i)_{i \in \mathbb{Z}}$ of D -module morphisms $d_i : M_i \rightarrow M_{i-1}$ is a *complex*, if $d_i \circ d_{i+1} = 0$ for all $i \in \mathbb{Z}$. We write:

$$\dots \xrightarrow{d_{i+2}} M_{i+1} \xrightarrow{d_{i+1}} M_i \xrightarrow{d_i} M_{i-1} \xrightarrow{d_{i-1}} \dots \quad (6)$$

The complex (6) is called *exact at position i* if the *defect of exactness of (6) at position i* ,

$$H(M_i) = \ker d_i / \text{im } d_{i+1},$$

is equal to 0 or, equivalently, if $\ker d_i = \text{im } d_{i+1}$. The complex (6) is called *exact* if it is exact at every position.

2. The exact sequence $0 \rightarrow M' \xrightarrow{f} M \xrightarrow{g} M'' \rightarrow 0$, i.e., where f is injective, g is surjective and $\ker g = \text{im } f$, is called a *short exact sequence*.

We recall some properties of D -modules that will be important in the course of the paper.

Definition 3.4. [33] Let D be an integral domain which is a left Ore ring and M a finitely generated left D -module.

1. The left D -module M is *free* if it is isomorphic to $D^{1 \times s}$ for a certain $s \in \mathbb{Z}_{\geq 0}$.
2. M is a *stably free* left D -module if there exist $r, s \in \mathbb{Z}_{\geq 0}$ such that $M \oplus D^{1 \times r} \cong D^{1 \times s}$.
3. M is a *projective* left D -module if there exist a left D -module N and $s \in \mathbb{Z}_{\geq 0}$ such that $M \oplus N \cong D^{1 \times s}$.
4. Define by $\text{hom}_D(M, D)$ the right D -module consisting of all D -morphisms $M \rightarrow D$. The set $\text{hom}_D(\text{hom}_D(M, D), D)$ is again a left D -module and there is a canonical map

$$\varepsilon_M : M \longrightarrow \text{hom}_D(\text{hom}_D(M, D), D), \quad \varepsilon_M(m)(f) = f(m),$$

$m \in M, f \in \text{hom}_D(M, D)$. If ε_M is an isomorphism, then M is called *reflexive* left D -module.

5. The set $t(M) = \{m \in M \mid \exists 0 \neq P \in D : Pm = 0\}$ is a left submodule of M which is called the *torsion submodule* of M . The non-zero elements of $t(M)$ are all the *torsion elements* of M .

6. The left D -module M is called *torsion-free* if its torsion submodule is trivial, i.e., $t(M) = 0$.

We have similar definitions for right D -modules over integral domains which are right Ore rings.

Let us notice that the fact that $t(M)$ is a (left/right) D -submodule of M implies that we have the short exact sequence:

$$0 \longrightarrow t(M) \longrightarrow M \longrightarrow M/t(M) \longrightarrow 0.$$

Proposition 3.5. [33] *Let D be an integral domain which is a (left/right) Ore ring and M be a finitely generated (left/right) D -module. Then, we have the following implications among these concepts:*

$$\text{free} \Rightarrow \text{projective} \Rightarrow \text{reflexive} \Rightarrow \text{torsion-free}.$$

Theorem 3.6. 1. [17, 33] *If D is a left hereditary ring – namely, every left ideal of D is a left projective D -module – (e.g., a commutative Dedekind domain, $D = A_1$), then every finitely generated torsion-free left D -module is projective. Moreover, if D is a left principal ideal domain – namely, every left ideal of D is principal – (e.g., $k[x]$ or $k(t)[\partial; \text{id}_{k(t)}, \frac{d}{dt}]$, where k is a field of constants), then every finitely generated torsion-free left D -module is free.*

2. [17, 33] *Every projective module over a commutative polynomial ring with coefficients in a field is free (Quillen-Suslin theorem).*

Definition 3.7. [33] A short exact sequence of (left/right) D -modules $0 \longrightarrow M' \xrightarrow{f} M \xrightarrow{g} M'' \longrightarrow 0$ is called a *split exact sequence* if one of the following equivalent conditions is satisfied:

- there exists an D -morphism $h : M'' \longrightarrow M$ such that $g \circ h = \text{id}_{M''}$,
- there exists an D -morphism $k : M \longrightarrow M'$ such that $k \circ f = \text{id}_{M'}$,
- the (left/right) D -module M is isomorphic to the direct sum of M' and M'' , which is denoted by $M \cong M' \oplus M''$, or equivalently, there exist two D -morphisms

$$\begin{cases} \phi = \begin{pmatrix} k \\ g \end{pmatrix} : M \longrightarrow M' \oplus M'', \\ \psi = (f : h) : M' \oplus M'' \longrightarrow M, \end{cases}$$

satisfying $\phi \circ \psi = \text{id}_{M' \oplus M''}$ and $\psi \circ \phi = \text{id}_M$.

Proposition 3.8. [4, 33] *If M'' is a (left/right) projective D -module and M' and M are (left/right) D -modules, then the short exact sequence $0 \longrightarrow M' \xrightarrow{f} M \xrightarrow{g} M'' \longrightarrow 0$ splits.*

In the course of the paper, we shall need the following classical lemma.

Lemma 3.9. [33] *Let D be a commutative noetherian ring, M a finitely generated D -module and S a multiplicatively closed subset of D (namely, $1 \in S$ and $\forall s_1, s_2 \in S \Rightarrow s_1 s_2 \in S$). Let us introduce the commutative noetherian ring $S^{-1}D = \{a/s \mid a \in D, s \in S\}$ and the $S^{-1}D$ -module $S^{-1}D \otimes_D M = \{m/s \mid m \in M, s \in S\}$. Then, we have:*

$$S^{-1}D \otimes_D \text{ext}_D^j(M, D) \cong \text{ext}_{S^{-1}D}^j(S^{-1}D \otimes_D M, S^{-1}D), \quad j \geq 0.$$

In the following sections, we shall develop effective algorithms based on Gröbner bases in order to check whether or not a left D -module M associated with a linear control system (e.g., the differential time-delay system (4)) is torsion-free, reflexive, ..., or free. In the next section, we shall give some system interpretations of these properties of modules.

4 System interpretations of module properties

In what follows, we shall not precise the Ore algebra D we use (e.g., if we study time-varying ordinary differential systems (resp. differential time-delay systems...), then $D = A_1$ (resp. $D = D_h$...)).

Let us give some system interpretations of the previous properties of modules by introducing some definitions which generalize to linear systems over Ore algebras some definitions commonly used in the literature for some particular classes of systems (e.g., ordinary/partial differential equations, differential time-delay systems). In the following definition and the next proposition, the references therein refer to the particular classes of systems for which these concepts have been firstly introduced.

Definition 4.1. • [25, 36] An *observable* of a linear control system $Ry = 0$ is a *scalar* D -linear combination of the components of y (i.e., of the system variables including inputs, states, outputs). An observable $\phi(y)$ is called *autonomous* if it satisfies some linear equation by itself, namely $P\phi(y) = 0$, where $0 \neq P \in D$. An observable is said to be *free* if it is not autonomous.

- [11, 25, 36] A linear control system is said to be *controllable* if every observable is free.
- [25, 26, 27] A linear control system $Ry = 0$ is *parametrizable* if there exist a matrix R_{-1} with entries in D and arbitrary functions z such that the compatibility conditions of the inhomogeneous system $y = R_{-1}z$ are exactly generated by $Ry = 0$ or, equivalently, if there exists $R_{-1} \in D^{p \times m}$ such that $M = D^{1 \times p}/D^{1 \times q} R \cong D^{1 \times p} R_{-1}$. Then, R_{-1} is called a *parametrization* of the system $Ry = 0$ and z is a *potential* of the system.
- [11, 20, 31] If a linear control system is parametrized by R_{-1} and there exist a matrix S_{-1} with entries in D and $0 \neq \pi \in D$ satisfying $S_{-1}R_{-1} = \pi I$, where I denotes the identity matrix, then the system is said to be π -*free*.
- [11, 20] A linear control system is *flat* (or *free*) if it is 1-free or, in other words, it is parametrizable and every component z_i of the potential z is an observable of the system or, equivalently, if there exists a parametrization $R_{-1} \in D^{p \times m}$ which admits a left-inverse $S_{-1} \in D^{m \times p}$, i.e., $S_{-1}R_{-1} = I_m$. Then, z is called a *flat output* of the system.

We refer to [36] for a nice survey on the duality existing between the module-theoretic approach [11, 20, 21, 25, 26, 27, 30] and the behavioural approach [10, 22, 23, 32, 37] to multidimensional systems. This duality was firstly observed and developed by U. Oberst in [18]. Let us notice that research of parametrizations for multidimensional linear systems is called the *image representation problem* in the behavioural approach.

Proposition 4.2. *Let D be an Ore algebra, $R \in D^{q \times p}$ and $M = D^{1 \times p}/D^{1 \times q} R$ the left D -module associated with the system $Ry = 0$ (see Definition 3.1).*

1. [25, 26, 36] *The observables of the system are in a one-to-one correspondence with the left D -module M .*
2. [11, 22, 25, 26, 36] *The autonomous elements of the system are in a one-to-one correspondence with the torsion elements of M .*
3. [11, 20, 22, 25, 26] *The system is controllable iff M is a torsion-free left D -module.*
4. [11, 20] *If D is a commutative polynomial ring, then the system is π -free iff there exists a polynomial $0 \neq \pi \in D$ such that $D_\pi \otimes_D M = \{m/a \mid m \in M, a = \pi^n, n \in \mathbb{Z}_{\geq 0}\}$ is a free $D_\pi = \{b/a \mid b \in D, a = \pi^n, n \in \mathbb{Z}_{\geq 0}\}$ -module.*
5. [11, 20] *The system is flat iff M is a free left D -module. Then, a basis of M is a flat output of the system.*

Let us recall the following well-known concepts of coprimeness developed in the literature of multidimensional systems. These concepts allow us to classify the systems.

Definition 4.3. [11, 18, 27, 37] Let $D = \mathbb{R}[x_1, \dots, x_n]$ be a commutative polynomial ring, R a full row rank matrix (namely, its rows are D -linearly independent) in $D^{q \times p}$, J the ideal generated by the $q \times q$ minors of R and $V(J) = \{\xi \in \mathbb{C}^n \mid \forall P \in J : P(\xi) = 0\}$ the algebraic variety defined by J . Then,

- R is called *minor left-prime* if $\dim_{\mathbb{C}} V(J) \leq n - 1$, i.e., the greatest common divisor of all the $q \times q$ minors of R is 1.
- R is called *weakly zero left-prime* if $\dim_{\mathbb{C}} V(J) \leq 0$, i.e., all the $q \times q$ minors of R may only vanish simultaneously in a finite number of points of \mathbb{C}^n .
- R is called *zero left-prime* if $\dim_{\mathbb{C}} V(J) = -1$, i.e., all the $q \times q$ minors of R do not vanish simultaneously in \mathbb{C}^n .

Theorem 4.4. [11, 18, 27] *Let $D = \mathbb{R}[x_1, \dots, x_n]$ be a commutative polynomial ring and R a full row rank matrix in $D^{q \times p}$. Then, we have:*

1. R is minor left-prime iff the D -module $M = D^{1 \times p} / D^{1 \times q} R$ is torsion-free.
2. If $n = 3$, then R is weakly zero left-prime iff the D -module $M = D^{1 \times p} / D^{1 \times q} R$ is reflexive.
3. R is zero left-prime iff the D -module $M = D^{1 \times p} / D^{1 \times q} R$ is free.

Hence, the concepts of torsion-freeness, reflexiveness, projectiveness and freeness generalize to non-commutative polynomial rings the well-known concepts of primeness developed for multidimensional systems [27]. The next sections are dedicated to giving effective algorithms which check the module properties and compute the parametrizations and flat outputs.

5 Syzygy modules and free resolutions

Let M be a finitely generated left module over a left noetherian ring D . We can reformulate the fact that M is finitely generated by saying that there exists a surjective D -morphism $\varphi : D^{1 \times p} \rightarrow M$ which maps the i th vector of the canonical basis $\{e_i\}_{1 \leq i \leq p}$ of $D^{1 \times p}$ to some $m_i \in M$. We have the exact sequence:

$$\begin{array}{ccccc} D^{1 \times p} & \xrightarrow{\varphi} & M & \longrightarrow & 0, \\ e_i & \longmapsto & m_i & & \end{array}$$

This map can fail to be injective since there can be linear relations among the $\{m_i\}_{1 \leq i \leq p}$:

$$\ker \varphi = \{P = (P_1 : \dots : P_p) \in D^{1 \times p} \mid \varphi(P) = \sum_{i=1}^p P_i \varphi(e_i) = \sum_{i=1}^p P_i m_i = 0\}. \quad (7)$$

Definition 5.1. [33] The D -linear relations among the m_1, \dots, m_p form the left D -module $S(M)$ defined by (7) which is called the *syzygy module* of M (this module is uniquely defined up to *projective equivalence* [33]). A similar definition exists for right D -modules.

Since D is a left noetherian ring, $S(M)$ is a finitely generated left D -module. Therefore, we can again find a suitable free D -module $D^{1 \times q}$ and a map ψ sending the canonical basis vectors of $D^{1 \times q}$ to a family of generators of $S(M)$ and we have the following exact sequence:

$$D^{1 \times q} \xrightarrow{\psi} D^{1 \times p} \xrightarrow{\varphi} M \longrightarrow 0.$$

This exact sequence is called a *finite presentation* of the left D -module M and M is said to be *finitely presented*. Let us notice that, w.r.t. the canonical (standard) bases of $D^{1 \times q}$ and $D^{1 \times p}$, ψ is defined by multiplication on the right with the matrix whose i th row corresponds to the i th generator of $S(M)$. Finally, iterating the preceding construction, we get the definition of a *free resolution* of the D -module M .

Definition 5.2. 1. [33] An exact sequence of the form

$$\dots \xrightarrow{d_3} P_2 \xrightarrow{d_2} P_1 \xrightarrow{d_1} P_0 \xrightarrow{d_0} M \longrightarrow 0 \quad (8)$$

is called a (left/right) *projective resolution* of M if the D -modules P_i are projective (left/right) D -modules. The (left/right) D -module $S_i(M) = \ker d_i$ is called the *i th syzygy module* of M .

2. [33] If the D -modules P_i in (8) are free, then (8) is a *free resolution* of M .
3. [33] Let $0 \longrightarrow P_n \xrightarrow{d_n} P_{n-1} \xrightarrow{d_{n-1}} \dots \xrightarrow{d_2} P_1 \xrightarrow{d_1} P_0 \xrightarrow{d_0} M \longrightarrow 0$ be a projective resolution of M . We define the *length* of this resolution to be n .
4. [33] The minimal length of a left (resp. right) projective resolution of M is called the *left (resp. right) projective dimension* $\text{pd}_D({}_D M)$ (resp. $\text{pd}_D(M_D)$) of the left (resp. right) D -module M . The (left/right) projective dimension can be infinite.
5. [33] We set $\text{lgld } D = \sup \{\text{pd}_D({}_D M) \mid M \text{ a left } D\text{-module}\} \in \mathbb{Z}_{\geq 0} \cup \{\infty\}$, which is called the *left global dimension* of D . Similarly for the *right global dimension* $\text{rgld } D$. If D is commutative, then we write $\text{gld } D = \text{lgld } D = \text{rgld } D$.

We describe the computational tools for the construction of free resolutions. The techniques to compute syzygy modules use Gröbner bases and elimination techniques (see Section 6.1 of [2]). Let D be an Ore algebra which satisfies (2) and L a finitely generated left D -module which is a submodule of a free D -module $D^{1 \times p}$, $p \in \mathbb{N}$. Thus, a set of generators of L consists of row vectors in $D^{1 \times p}$.

Algorithm 5.3.

Input: Set of generators $\{R_1, \dots, R_q\} \subset D^{1 \times p}$ of the left D -module L ,
where $R_i = (R_{i1} : \dots : R_{ip})$, $i = 1, \dots, q$.

Output: $S \in D^{r \times q}$ such that the left D -module $D^{1 \times r} S$ is the syzygy module $S(L)$ of L .

SYZYGIES (R_1, \dots, R_q)

Introduce the indeterminates $\lambda_1, \dots, \lambda_p, \mu_1, \dots, \mu_q$ over D .

$P \leftarrow \{\sum_{j=1}^p R_{ij} \lambda_j - \mu_i \mid i = 1, \dots, q\}$.

Compute the Gröbner basis G of P in the free left D -module generated by $\lambda_1, \dots, \lambda_p, \mu_1, \dots, \mu_q$,
namely $\bigoplus_{i=1}^p D \lambda_i \oplus \bigoplus_{i=1}^q D \mu_i$, w.r.t. an order which eliminates the λ_i 's.

$S = (S_{ij}) \in D^{r \times q} \leftarrow G \cap \bigoplus_{i=1}^q D \mu_i = \{\sum_{j=1}^q S_{ij} \mu_j \mid i = 1, \dots, r\}$.

Remark 5.4. Let us suppose that we have $R \in D^{q \times p}$ and the left D -module $M = D^{1 \times p} / D^{1 \times q} R$. Then, we can apply the preceding algorithm to the set formed by

$$R_i = (R_{i1} : \dots : R_{ip}) \in L = D^{1 \times q} R \subseteq D^{1 \times p}, \quad i = 1, \dots, q,$$

in order to obtain the matrix $S = (S_{ij}) \in D^{r \times q}$ such that

$$S(M) = \ker \cdot R = \{(P_1 : \dots : P_q) \in D^{1 \times q} \mid \sum_{i=1}^q P_i R_i = 0\} = D^{1 \times r} S$$

and we obtain the exact sequence $D^{1 \times r} \xrightarrow{\cdot S} D^{1 \times q} \xrightarrow{\cdot R} D^{1 \times p} \xrightarrow{\pi} M \longrightarrow 0$. Iterating the process, we obtain a free resolution of the left D -module M .

For further developments and optimization of the technique, see [14].

Example 5.5. Let D_h be the differential time-delay Ore algebra introduced in Example 3.2, $R \in D_h^{3 \times 4}$ defined by (5) and the D_h -module $L = D_h^{1 \times 4} R^T$ generated by the rows of the matrix:

$$R^T = \begin{pmatrix} \partial + a & 0 & 0 \\ -k a \delta_h & \partial & \omega^2 \\ 0 & -1 & \partial + 2 \zeta \omega \\ 0 & 0 & -\omega^2 \end{pmatrix} \in D_h^{4 \times 3}.$$

We shall see later that the transposed matrix R^T plays an important role in the characterization of the algebraic properties of the D_h -module $M = D_h^{1 \times 4} / D_h^{1 \times 3} R$. Let us compute the syzygy module of the D_h -module L . The reduced Gröbner basis of

$$P = \{(\partial + a) \lambda_1 - \mu_1, -k a \delta_h \lambda_1 + \partial \lambda_2 + \omega^2 \lambda_3 - \mu_2, -\lambda_2 + (\partial + 2 \zeta \omega) \lambda_3 - \mu_3, -\omega^2 \lambda_3 - \mu_4\}$$

w.r.t. the elimination ordering induced by the degree reverse lexicographical orderings on $\lambda_1 > \lambda_2 > \lambda_3$ and $\mu_1 > \mu_2 > \mu_3 > \mu_4 > \delta_h > \partial$ resp. is:

$$G = \{\omega^2 \lambda_2 + \partial \mu_4 + \omega^2 \mu_3 + 2 \zeta \omega \mu_4, \omega^2 k a \delta_h \lambda_1 + \omega^2 \mu_2 + \omega^2 \partial \mu_3 + (\partial^2 + 2 \zeta \omega \partial + \omega^2) \mu_4, \\ \omega^2 k a \delta_h \mu_1 + (\omega^2 \partial + \omega^2 a) \mu_2 + (\omega^2 \partial^2 + \omega^2 a \partial) \mu_3 + (\partial^3 + (2 \zeta \omega + a) \partial^2 + (\omega^2 + 2 a \zeta \omega) \partial \\ + a \omega^2) \mu_4, (\partial + a) \lambda_1 - \mu_1, \omega^2 \lambda_3 + \mu_4\}.$$

Intersecting G with $\bigoplus_{i=1}^4 D \mu_i$ we get

$$S = \{\omega^2 k a \delta_h \mu_1 + (\omega^2 \partial + \omega^2 a) \mu_2 + (\omega^2 \partial^2 + \omega^2 a \partial) \mu_3 + (\partial^3 + (2 \zeta \omega + a) \partial^2 + \\ (\omega^2 + 2 a \zeta \omega) \partial + a \omega^2) \mu_4\}.$$

If we denote by R_{-1}^T the following row vector with entries in D_h

$$R_{-1}^T = (\omega^2 k a \delta_h : \omega^2 \partial + \omega^2 a : \omega^2 \partial^2 + \omega^2 a \partial : \partial^3 + (2 \zeta \omega + a) \partial^2 + (\omega^2 + 2 a \zeta \omega) \partial + a \omega^2),$$

then we obtain the following free resolution of the D_h -module $N = D_h^{1 \times 3} / D_h^{1 \times 4} R^T$:

$$0 \longrightarrow D_h \xrightarrow{\cdot R_{-1}^T} D_h^{1 \times 4} \xrightarrow{\cdot R^T} D_h^{1 \times 3} \xrightarrow{\pi} N \longrightarrow 0. \quad (9)$$

We conclude this section by giving examples of left (right) global dimensions and by stating that free resolutions of finite length exist for every finitely generated module over Ore algebras $D = A[\partial_1; \sigma_1, \delta_1] \dots [\partial_m; \sigma_m, \delta_m]$, where all σ_i are automorphisms. Note that every Ore algebra that we consider is of this kind (see e.g., Examples 2.3, 2.4, and 2.5).

Proposition 5.6. [17] *Let A be an integral domain with a finite left (resp. right) global dimension $\text{lgld } A$ (resp. $\text{rgld } A$) and σ an automorphism of A .*

1. *The left (resp. right) global dimension of $A[\partial; \sigma, \delta]$ satisfies:*

$$\text{lgld } A \leq \text{lgld } A[\partial; \sigma, \delta] \leq \text{lgld } A + 1 \quad (\text{rgld } A \leq \text{rgld } A[\partial; \sigma, \delta] \leq \text{rgld } A + 1).$$

If $\delta = 0$, then we have:

$$\text{lgld } A[\partial; \sigma, 0] = \text{lgld } A + 1 \quad (\text{rgld } A[\partial; \sigma, 0] = \text{rgld } A + 1).$$

2. *If k is a field, then we have $\text{lgld } k[x_1, \dots, x_n] = \text{rgld } k[x_1, \dots, x_n] = n$ and the Weyl algebra A_n (see Example 2.3) satisfies $\text{lgld } A_n = \text{rgld } A_n = n$ if k is a field of characteristic 0 and $\text{lgld } A_n = \text{rgld } A_n = 2n$ if k is a field of characteristic $p > 0$.*

Example 5.7. By the preceding proposition, the Ore algebra S_h of Example 2.4 has left (resp. right) global dimension 2 because $\text{lgld } k[t] = \text{rgld } k[t] = 1$. For the Ore algebra D_h of Example 2.5, we have $\text{lgld } D_h = \text{rgld } D_h = 2$ since $k[t][\partial; \sigma_1, \delta_1] = A_1$ has left (resp. right) global dimension 1 and $\delta_2 = 0$.

Let us notice that we do not know examples of rings satisfying $\text{lgld } A[\partial; \sigma, \delta] = \text{lgld } A$.

Proposition 5.8. [17, 33] *Let $D = A[\partial_1; \sigma_1, \delta_1] \dots [\partial_m; \sigma_m, \delta_m]$ be an Ore algebra, where σ_i is an automorphism, $i = 1, \dots, m$, and M a finitely generated (left/right) D -module. Then, there is a free resolution of M of length less than or equal $\text{lgld } D + 1$ (resp. $\text{rgld } D + 1$).*

Proof. Iteratively applying Corollary 3.3 of [17] according to the construction of D from the field k , it follows that every finitely generated projective (left/right) D -module P is stably free. Since D has finite (left/right) global dimension according to Proposition 5.6, M has a projective resolution (8) of length less or equal to $\text{lgld } D$ (resp. $\text{rgld } D$), where all P_i are finitely generated projective, i.e., stably free (left/right) D -modules. Now, Lemma 9.40 of [33] states that, if M has a *stably free resolution* of length n , namely a resolution of the form (8) where every F_i is a stably free (left/right) D -module, then M has a free resolution of length less or equal to $n + 1$. Hence, we conclude that M has a free resolution of length less or equal to $\text{lgld } D + 1$ (resp. $\text{rgld } D + 1$). \square

Let us notice that the previous result is a reminiscence of the concept of a *Janet sequence* developed in the theory of differential operators [25].

6 Involutions

Definition 6.1. Let k be a field and D a (non-commutative) k -algebra. An *involution* θ of D is a k -linear map $\theta : D \rightarrow D$ satisfying

$$\begin{aligned} \theta(a_1 \cdot a_2) &= \theta(a_2) \cdot \theta(a_1), & a_1, a_2 \in D, \\ \theta \circ \theta &= \text{id}_D, \end{aligned} \tag{10}$$

i.e., θ is an anti-automorphism of order two of the k -algebra D .

Proposition 6.2. *By means of an involution θ of D , left D -modules can be turned into right D -modules and vice versa: let D be a k -algebra, M a right D -module and θ an involution of D , then we can define the left D -module \widetilde{M} , which is equal to M as a set and which is endowed with the same addition as M , but with the following left action of D :*

$$a m = m \theta(a), \quad m \in \widetilde{M}, \quad a \in D.$$

Property (10) of θ ensures that \widetilde{M} is a well-defined left D -module.

Example 6.3. 1. Let D be a commutative ring (e.g., $D = k[x_1, \dots, x_n]$). Then, $\theta = id_D$ is a trivial involution of D .

2. Let $A_n = k[x_1, \dots, x_n][\partial_1; \sigma_1, \delta_1] \dots [\partial_n; \sigma_n, \delta_n]$ be the Weyl algebra (see Example 2.3). An involution θ of A_n can be defined by $x_i \mapsto x_i$, $\partial_i \mapsto -\partial_i$, $1 \leq i \leq n$.

3. Let $S_h = k[t][\delta_h; \sigma_h, \delta]$ be the shift Ore algebra (see Example 2.4). An involution θ of S_h can be defined by $t \mapsto -t$, $\delta_h \mapsto \delta_h$.

4. Let $H_h = k[t][\partial; \sigma_1, \delta_1][\delta_h; \sigma_2, \delta_2][\tau_h; \sigma_3, \delta_3]$ be the Ore algebra of differential time-delay and advance operators (see Example 2.5 for more details). An involution θ of H_h can be defined by $t \mapsto t$, $\partial \mapsto -\partial$, $\delta_h \mapsto \tau_h$, $\tau_h \mapsto \delta_h$.

5. We can prove that there is no non-trivial involution for the Ore algebra D_h of differential time-delay operators (see Example 2.5). Therefore, we need to embed D_h into the Ore algebra H_h of differential time-delay and advance operators.

Definition 6.4. Let D be a left Ore algebra with an involution θ , $R \in D^{q \times p}$ and $M = D^{1 \times p} / D^{1 \times q} R$ a left D -module.

- The *dual* M^* of M is the right D -module defined by $\text{hom}_D(M, D)$.
- The *transposed module* of M is the right D -module defined by:

$$N = D^q / R D^p.$$

If D is a commutative ring, then we have $N = D^{1 \times q} / D^{1 \times p} R^T$, which explains the terminology.

- The *adjoint module* of M is the left D -module defined by

$$\tilde{N} = D^{1 \times q} / D^{1 \times p} \theta(R),$$

where $\theta(R)$ is the transpose of the matrix obtained by applying θ to each of its entries, i.e.:

$$\theta(R) = (\theta(R_{ij}))_{1 \leq i \leq q, 1 \leq j \leq p}^T.$$

Hence, the left D -module $\tilde{N} = D^{1 \times q} / D^{1 \times p} \theta(R)$ corresponds to the linear system $\theta(R)z = 0$, where $z = (z_1 : \dots : z_q)^T$.

Example 6.5. 1. If D is a commutative ring (e.g., $D_h = \mathbb{R}(a, k, \zeta, \omega)[\partial; \sigma_1, \delta_1][\delta_h; \sigma_2, \delta_2]$ defined in Example 3.2), then the involution θ is just the transposition of matrices, namely $\theta(R) = R^T$, and the transposed D -module is defined by $\tilde{N} = D^{1 \times q} / D^{1 \times p} R^T = D^q / R D^p = N$.

2. Let us consider the Ore algebra $H_h = k[t][\partial; \sigma_1, \delta_1][\delta_h; \sigma_2, \delta_2][\tau_h; \sigma_3, \delta_3]$ defined in Example 2.5 and $R = [t \partial : -t^2 \delta_h] \in H_h^{1 \times 2}$. Then, using 4 of Example 6.3, we obtain:

$$\theta(R) = \begin{pmatrix} -\partial t \\ -\tau_h t^2 \end{pmatrix} = \begin{pmatrix} -t \partial - 1 \\ -(t+h)^2 \tau_h \end{pmatrix} \in H_h^{2 \times 1}.$$

7 Computation of extension modules

Definition 7.1. [33] Let M be a finitely generated left D -module, M' a left D -module and

$$\dots \xrightarrow{d_2} F_1 \xrightarrow{d_1} F_0 \xrightarrow{d_0} M \longrightarrow 0$$

a free resolution of M . Then, the defects of exactness of the complex

$$\dots \longleftarrow \text{hom}_D(F_2, M') \xleftarrow{d_2^*} \text{hom}_D(F_1, M') \xleftarrow{d_1^*} \text{hom}_D(F_0, M') \longleftarrow 0,$$

where d_i^* is defined by $d_i^*(f) = f \circ d_i$ for $f \in \text{hom}_D(F_{i-1}, M')$, $i \geq 1$, are defined by the abelian groups:

$$\begin{cases} \text{ext}_D^0(M, M') &= \ker d_1^* = \text{hom}_D(M, M'), \\ \text{ext}_D^i(M, M') &= \ker d_{i+1}^* / \text{im } d_i^*, \quad i \geq 1. \end{cases}$$

In the following, we shall only consider the case $M' = D$, and thus, $\text{ext}_D^i(M, D)$, $i \in \mathbb{Z}_{\geq 0}$. Let us notice that $\text{ext}_D^i(M, D)$, $i \in \mathbb{Z}_{\geq 0}$, inherit a right module structure by the right action of D .

Proposition 7.2. [33] *The right D -module $\text{ext}_D^i(M, D)$ only depends on M , i.e., we can choose any free resolution of M to compute $\text{ext}_D^i(M, D)$, $i \in \mathbb{Z}_{\geq 0}$.*

The next algorithm gives a description of the left D -module $\text{ext}_D^1(\widetilde{M}, D)$, which corresponds to the right D -module $\text{ext}_D^1(M, D)$ (see Proposition 6.2).

Algorithm 7.3.

Input: Ore algebra D satisfying (2) with an involution θ and $R = (R_1^T : \dots : R_q^T)^T \in D^{q \times p}$.

Output: A list $L = (L_1, L_2)$ of two matrices such that:

$L_1 \in D^{m \times q}$ is such that $\text{ext}_D^1(\widetilde{M}, D) = D^{1 \times m} L_1 / D^{1 \times p} \theta(R)$, where $M = D^{1 \times p} / D^{1 \times q} R$,
 $L_2 \in D^{q \times r}$ is such that $L_1 = \text{SYZYGIES}(L_2)$.

ADJEXT1(R)

$R_2 \leftarrow \text{SYZYGIES}(R)$,

$L_2 \leftarrow \theta(R_2)$,

$L_1 \leftarrow \text{SYZYGIES}(L_2)$,

$L \leftarrow (L_1, L_2)$.

Proof. The module M is given as the cokernel $D^{1 \times p} / D^{1 \times q} R$ of the D -linear map:

$$D^{1 \times q} \xrightarrow{\cdot R} D^{1 \times p}.$$

Computing the first syzygy module of M , we obtain a matrix $R_2 \in D^{r \times q}$ such that the sequence

$$D^{1 \times r} \xrightarrow{\cdot R_2} D^{1 \times q} \xrightarrow{\cdot R} D^{1 \times p}$$

is exact. Upon dualization, we get the complex

$$D^{r \times 1} \xleftarrow{\cdot R_2} D^{q \times 1} \xleftarrow{\cdot R} D^{p \times 1}$$

with defect of exactness $\text{ext}_D^1(M, D) = \ker(R_2 \cdot) / R D^{p \times 1}$ at $D^{q \times 1}$. Taking adjoints and writing $L_2 = \theta(R_2) \in D^{q \times r}$, we obtain the complex

$$D^{1 \times r} \xleftarrow{\cdot L_2} D^{1 \times q} \xleftarrow{\cdot \theta(R)} D^{1 \times p}$$

with defect of exactness $\text{ext}_D^1(\widetilde{M}, D)$. Computing the first syzygy module of $\text{coker}(\cdot L_2)$ yields the exact sequence

$$D^{1 \times r} \xleftarrow{\cdot L_2} D^{1 \times q} \xleftarrow{\cdot L_1} D^{1 \times m}$$

such that:

$$\text{ext}_D^1(\widetilde{M}, D) = \ker(\cdot L_2) / D^{1 \times p} \theta(R) = D^{1 \times m} L_1 / D^{1 \times p} \theta(R).$$

□

Example 7.4. Let us compute $\text{ext}_{D_h}^i(N, D_h)$ of the D_h -module N defined in Example 5.5. In Example 5.5, we have already computed the free resolution (9) of $N = D_h^{1 \times 3} / D_h^{1 \times 4} R^T$. Thus, we have $\ker \cdot R^T = D_h R_{-1}^T$, where R_{-1}^T is defined in Example 5.5. Then, using the fact that $D_h = \mathbb{R}(a, k, \zeta, \omega)[\partial; \sigma_1, \delta_1][\delta_h; \sigma_2, \delta_2]$ is a commutative polynomial ring, we obtain that $\theta(R_{-1}^T) = R_{-1}$ (see 1 of Example 6.3). Hence, we have the following complex

$$0 \longleftarrow D_h \xleftarrow{\cdot R_{-1}} D_h^{1 \times 4} \xleftarrow{\cdot R} D_h^{1 \times 3} \longleftarrow 0$$

and its defects of exactness are defined by:

$$\text{ext}_{D_h}^1(N, D_h) = \ker \cdot R_{-1} / D_h^{1 \times 3} R, \quad (11)$$

$$\text{ext}_{D_h}^2(N, D_h) = D_h / D_h^{1 \times 4} R_{-1}. \quad (12)$$

Following Algorithm 7.3, we need to compute the syzygy module of $D_h^{1 \times 4} R_{-1}$. The reduced Gröbner basis of

$$P = \{ (\omega^2 k a \delta_h) \lambda - \mu_1, (\omega^2 \partial + \omega^2 a) \lambda - \mu_2, (\omega^2 \partial^2 + \omega^2 a \partial) \lambda - \mu_3, \\ (\partial^3 + 2 \zeta \omega \partial^2 + a \partial^2 + \omega^2 \partial + 2 a \zeta \omega \partial + a \omega^2) \lambda - \mu_4 \}$$

w.r.t. the elimination ordering induced by the degree reverse lexicographical orderings on λ and $\mu_1 > \mu_2 > \mu_3 > \mu_4 > \delta_h > \partial$ resp. is:

$$G = \{ (\partial + a) \mu_1 - k a \delta \mu_2, \omega^2 \mu_2 + (\partial + 2 \zeta \omega) \mu_3 - \omega^2 \mu_4, \partial \mu_2 - \mu_3, \\ \omega^2 (\partial + a) \lambda - \mu_2, \omega^2 k a \delta \lambda - \mu_1 \}.$$

Therefore, we obtain that the syzygy module of $D_h^{1 \times 4} R_{-1}$ is defined by the matrix

$$L = \begin{pmatrix} \partial + a & -k a \delta_h & 0 & 0 \\ 0 & \omega^2 & \partial + 2 \zeta \omega & -\omega^2 \\ 0 & 0 & \partial & -1 \\ 0 & 0 & 0 & 0 \end{pmatrix} \in D_h^{3 \times 4}, \quad (13)$$

and thus, we have $\text{ext}_{D_h}^1(N, D_h) = D_h^{1 \times 3} L / D_h^{1 \times 3} R$. Finally, using (12), $\text{ext}_{D_h}^2(N, D_h)$ corresponds to the system associated with $R_{-1} z = 0$, namely:

$$\begin{cases} (\omega^2 k a \delta_h) y = 0, \\ (\omega^2 \partial + \omega^2 a) y = 0, \\ (\omega^2 \partial^2 + \omega^2 a \partial) y = 0, \\ (\partial^3 + (2 \zeta \omega + a) \partial^2 + (\omega^2 + 2 a \zeta \omega) \partial + a \omega^2) y = 0. \end{cases} \quad (14)$$

Note that $\text{ext}_{D_h}^2(N, D_h) \neq 0$ because, otherwise, in G , we would have had $\lambda - \sum_{i=1}^4 P_i \mu_i$, for some $P_i \in D_h$.

The quotient module $\text{ext}_D^1(\widetilde{M}, D) = D^{1 \times m} L_1 / D^{1 \times p} \theta(R)$ can be computed using elimination techniques similar to Algorithm 5.3.

Algorithm 7.5.

Input: $R \in D^{q \times p}$ and $L_1 = (l_1^T : \dots : l_m^T)^T \in D^{m \times q}$ computed by `ADJEXT1`(R).

Output: A set S of generating equations satisfied by the residue class z_i of l_i^T in the left D -module $D^{1 \times m} L_1 / D^{1 \times p} \theta(R)$.

QUOTIENT(L_1, R)

Introduce the indeterminates $\lambda_1, \dots, \lambda_q$ and μ_1, \dots, μ_m over D .

Compute $\theta(R)$.

for $i = 1, \dots, m$ **do**

$L \leftarrow \{ \sum_{j=1}^q l_{ij} \lambda_j - \mu_i \} \cup \{ \sum_{j=1}^q \theta(R)_{kj} \lambda_j \mid k = 1, \dots, p \}$

Compute the Gröbner basis G_i of L in $\bigoplus_{j=1}^q D \lambda_j \oplus D \mu_i$
w.r.t. an order which eliminates the λ_j 's.

endfor

$S \leftarrow \bigcup_{i=1}^m (G_i \cap D \mu_i)$.

Remark 7.6. In the result of the preceding algorithm, each $G_i \cap D \mu_i$ is a generating set of the relations fulfilled by z_i . Let us notice that every polynomial in $G_i \cap D \mu_i$ has the form $P \mu_i$, for a certain $P \in D$.

Example 7.7. In Example 7.4, we proved that $\text{ext}_{D_h}^1(N, D_h) = D_h^{1 \times 3} L / D_h^{1 \times 3} R$, where R (resp. L) is defined by (5) (resp. (13)), $N = D_h^{1 \times 3} / D_h^{1 \times 4} R^T$ and $D_h = \mathbb{R}(a, k, \zeta, \omega)[\partial; \sigma_1, \delta_1][\delta_h; \sigma_2, \delta_2]$. In order to check whether or not $\text{ext}_{D_h}^1(N, D_h)$ is equal to 0, we apply `QUOTIENT`(L, R) described in Algorithm 7.5. If we denote

$$R = (R_1^T : R_2^T : R_3^T)^T, \quad L = (l_1^T : l_2^T : l_3^T)^T,$$

then we easily check that we have $G_i \cap D \mu_i = \{ \mu_i \}$, for $i = 1, \dots, 3$, because we have $l_1 = R_1, l_2 = R_3, l_3 = R_2$. Hence, we have $D_h^{1 \times 3} L = D_h^{1 \times 3} R$, which shows that $\text{ext}_{D_h}^1(N, D_h) = D_h^{1 \times 3} L / D_h^{1 \times 3} R = 0$.

The next algorithm gives a description of $\text{ext}_D^1(\widetilde{M}, D) = D^{1 \times m} L_1 / D^{1 \times p} \theta(R)$ in which the quotient is explicitly computed.

Algorithm 7.8.**Input:** An Ore algebra D satisfying (2) with an involution θ and $R = (R_1^T : \dots : R_q^T)^T \in D^{q \times p}$.**Output:** A tuple $L = (L_0, L_1, L_2)$ such that: $L_1 = \widetilde{(l_1^T : \dots : l_m^T)^T} \in D^{m \times q}$ is such that $\text{ext}_D^1(M, D) = D^{1 \times m} L_1 / D^{1 \times p} \theta(R)$, where $M = D^{1 \times p} / D^{1 \times q} R$, $L_2 \in D^{q \times r}$ is such that $L_1 = \text{SYZYGIES}(L_2)$, L_0 is the set of the relations satisfied by the residue class z_i of l_i^T in the left D -module $D^{1 \times m} L_1 / D^{1 \times p} \theta(R)$.EXT1(R) $(L_1, L_2) \leftarrow \text{ADJEXT}(R)$, $L_0 \leftarrow \text{QUOTIENT}(L_1, R)$, $L \leftarrow (L_0, L_1, L_2)$.**Remark 7.9.** First of all, if L_0 is an identity matrix, then we have $\text{ext}_D^1(M, D) = 0$ (e.g., see Example 7.7). Secondly, let us notice that while using EXT1, we start to compute a free resolution of the left D -module M (see Algorithm 7.3). If we denote this resolution by

$$\dots \xrightarrow{\cdot R_3} D^{1 \times p_2} \xrightarrow{\cdot R_2} D^{1 \times p_1} \xrightarrow{\cdot R_1} D^{1 \times p_0} \xrightarrow{\pi} M \longrightarrow 0,$$

where $p_0 = p$, $p_1 = q$ and $R_1 = R$, then $\text{EXT1}(R_i)$ computes $\widetilde{\text{ext}_D^i(M, D)}$, $i \geq 1$.

8 Characterization of module properties

The main motivation for introducing the concept of extension functor is explained in the next theorems which give an effective way to check the module properties defined in Section 3, and thus, the structural properties of the corresponding linear control system (see Section 4).

Definition 8.1. Let A and B be two rings and M an abelian group. M is said to be an A - B -bimodule, denoted ${}_A M_B$ if M is a left A -module and a right B -module and the two actions are related by the following associative law $\forall a \in A, \forall b \in B, \forall m \in M, a(m b) = (a m) b$.In this section, D is supposed to be a left and a right noetherian integral domain having the left and right Ore properties (see Proposition 2.7). Let us recall a classical result in homological algebra saying that a short exact sequence of bimodules gives rise to a long exact sequence of the cohomology right modules.**Lemma 8.2.** [33] Let N be a left D -module and $0 \longrightarrow A \longrightarrow B \longrightarrow C \longrightarrow 0$ an exact sequence of D - D -bimodules. Then, we have the following exact sequence of right D -modules:

$$\begin{array}{ccccccc} 0 & \longrightarrow & \text{hom}_D(N, A) & \longrightarrow & \text{hom}_D(N, B) & \longrightarrow & \text{hom}_D(N, C) \\ & & \longrightarrow & & \longrightarrow & & \longrightarrow \\ & & \text{ext}_D^1(N, A) & \longrightarrow & \text{ext}_D^1(N, B) & \longrightarrow & \text{ext}_D^1(N, C) \\ & & \longrightarrow & & \longrightarrow & & \dots \end{array}$$

Theorem 8.3. [29] Let M be a left D -module defined by the finite presentation

$$F_1 \xrightarrow{d_1} F_0 \longrightarrow M \longrightarrow 0, \quad (15)$$

and the right D -module N the transposed module of M defined by:

$$0 \longleftarrow N \longleftarrow F_1^* \xleftarrow{d_1^*} F_0^* \longleftarrow M^* \longleftarrow 0. \quad (16)$$

Then $t(M) \cong \text{ext}_D^1(N, D)$. In particular, M is a torsion-free left D -module iff $\text{ext}_D^1(N, D) = 0$.*Proof.* Let X be a D - D -bimodule. Then, applying the right exact functor $X \otimes_D \cdot$ [4, 33] to the exact sequence (15) gives the exact sequence

$$X \otimes_D F_1 \xrightarrow{\text{id}_X \otimes d_1} X \otimes_D F_0 \longrightarrow X \otimes_D M \longrightarrow 0,$$

whereas applying the left exact functor $\text{hom}(\cdot, X)$ to the exact sequence (16) yields the exact sequence:

$$0 \longrightarrow \text{hom}_D(N, X) \longrightarrow \text{hom}_D(F_1^*, X) \longrightarrow \text{hom}_D(F_0^*, X).$$

Using that the F_i are finitely generated free left D -modules, we have $\text{hom}_D(F_i^*, X) \cong X \otimes_D F_i$ [33], for $i = 1, 2$, and thus, we finally obtain the following exact sequence:

$$0 \longrightarrow \text{hom}_D(N, X) \longrightarrow X \otimes_D F_1 \longrightarrow X \otimes_D F_0 \longrightarrow X \otimes_D M \longrightarrow 0. \quad (17)$$

Now, let $K = Q(D)$ be the quotient field of D with its bimodule structure and let us consider the exact sequence of D - D -bimodules:

$$0 \longrightarrow D \longrightarrow K \longrightarrow K/D \longrightarrow 0. \quad (18)$$

Using Lemma 8.2 with $A = D$, $B = K$, $C = K/D$, we get the exact sequence of right D -modules

$$0 \longrightarrow \text{hom}_D(N, D) \longrightarrow \text{hom}_D(N, K) \longrightarrow \text{hom}_D(N, K/D) \longrightarrow \text{ext}_D^1(N, D) \longrightarrow 0, \quad (19)$$

because $\text{ext}_D^1(N, K) = 0$ since K is a left *injective* D -module (see [33] for more details).

Moreover, by applying the right exact functor $\cdot \otimes_D M$ to the short exact sequence (18), we obtain the exact sequence of left D -modules

$$M \xrightarrow{i_K} K \otimes_D M \longrightarrow (K/D) \otimes_D M \longrightarrow 0,$$

which extends to the following exact sequence:

$$0 \longrightarrow t(M) \longrightarrow M \xrightarrow{i_K} K \otimes_D M \longrightarrow (K/D) \otimes_D M \longrightarrow 0, \quad (20)$$

where the kernel of the D -morphism i_K , defined by $\{m \in M \mid i_K(m) = 1 \otimes m = 0\}$, is the left submodule of M formed by all elements $m \in M$ for which there exists $0 \neq d \in D$ such that $dm = 0$, i.e., the torsion submodule $t(M)$ of M [33].

Using the fact that the F_i are finitely generated free left D -modules, and thus, *flat* left D -modules [4, 33], by applying $\cdot \otimes_D F_i$ to the exact sequence (18), we obtain the exact sequence:

$$0 \longrightarrow F_i \longrightarrow K \otimes_D F_i \longrightarrow (K/D) \otimes_D F_i \longrightarrow 0. \quad (21)$$

Finally, combining together the exact sequences (17) for $X = D, K$ and K/D , (19), (20) and (21), we obtain the following commutative exact diagram:

$$\begin{array}{ccccccc} & & & & & & 0 \\ & & & & & & \downarrow \\ & & & & & & t(M) \\ & & & & & & \downarrow \\ 0 & \longrightarrow & \text{hom}_D(N, D) & \longrightarrow & \text{hom}_D(N, K) & \longrightarrow & \text{hom}_D(N, K/D) & \longrightarrow & \text{ext}_D^1(N, D) & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \text{hom}_D(N, D) & \longrightarrow & \text{hom}_D(N, K) & \longrightarrow & \text{hom}_D(N, K/D) & \longrightarrow & \text{ext}_D^1(N, D) & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \text{hom}_D(N, D) & \longrightarrow & \text{hom}_D(N, K) & \longrightarrow & \text{hom}_D(N, K/D) & \longrightarrow & \text{ext}_D^1(N, D) & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\ & & 0 & & 0 & & 0 & & 0 & & \end{array}$$

Then, an easy chase in the previous commutative exact diagram shows that $t(M) \cong \text{ext}_D^1(N, D)$. \square

Lemma 8.4. [4] *If $M_1 \xrightarrow{\alpha_1} M_2 \xrightarrow{\alpha_2} M_3 \xrightarrow{\alpha_3} M_4$ is a complex of (left/right) D -modules, then we have an exact ker-coker sequence induced by the map α_2*

$$0 \longrightarrow H(M_2) \longrightarrow \text{coker } \alpha_1 \longrightarrow \ker \alpha_3 \longrightarrow \ker H(M_3) \longrightarrow 0,$$

where $H(M_i)$ is the defect of exactness of the complex at M_i , namely $H(M_i) = \ker \alpha_i / \text{im } \alpha_{i-1}$, $i = 2, 3$, and $\text{coker } \alpha_1 = M_2 / \text{im } \alpha_1$.

Theorem 8.5. *Let M be a finitely presented left D -module, i.e., defined by the finite presentation (15), and N the transposed module of M defined by the finite presentation (16). Then, we have the following exact sequence:*

$$0 \longrightarrow \text{ext}_D^1(N, D) \longrightarrow M \xrightarrow{\varepsilon_M} M^{**} \longrightarrow \text{ext}_D^2(N, D) \longrightarrow 0. \quad (22)$$

Hence, M is a reflexive left D -module iff $\text{ext}_D^i(N, D) = 0$, $i = 1, 2$.

Proof. Let (15) be a finite presentation of M . Then, its transposed module is defined by $N = \text{coker } d_1^*$ in the exact sequence (16). We extend this finite presentation to an exact sequence by computing the second and the third syzygy module of N . We obtain the following exact sequence:

$$0 \longleftarrow N \longleftarrow F_1^* \xleftarrow{d_1^*} F_0^* \xleftarrow{d_0^*} F_{-1}^* \xleftarrow{d_{-1}^*} F_{-2}^*. \quad (23)$$

Dualizing the exact sequence (23) and using the fact that F_i is canonically isomorphic to F_i^{**} because the F_i are finitely generated free left D -modules, we obtain the following complex

$$F_1 \xrightarrow{d_1} F_0 \xrightarrow{d_0} F_{-1} \xrightarrow{d_{-1}} F_{-2}. \quad (24)$$

Now, applying Lemma 8.4 to the complex (24) and using the definitions of $\text{ext}_D^1(N, D)$ and $\text{ext}_D^2(N, D)$, we obtain the exact sequence:

$$0 \longrightarrow \text{ext}_D^1(N, D) \longrightarrow \text{coker } d_1 \longrightarrow \ker d_{-1} \longrightarrow \text{ext}_D^2(N, D) \longrightarrow 0.$$

According to the presentation of M , we have $M = \text{coker } d_1$. Now, using the exact sequences (16) and (23), we obtain the following exact sequence:

$$0 \longleftarrow M^* = \ker d_1^* \longleftarrow F_{-1}^* \xleftarrow{d_{-1}^*} F_{-2}^*. \quad (25)$$

By applying the left exact functor $\text{hom}_D(\cdot, D)$ to (25) [4, 33], we obtain the following exact sequence

$$0 \longrightarrow M^{**} \longrightarrow F_{-1} \xrightarrow{d_{-1}} F_{-2},$$

proving that $M^{**} = \ker d_{-1}$. Finally, we have the exact sequence (22), which proves that $M \cong M^{**}$ iff $\text{ext}_D^i(N, D) = 0$, $i = 1, 2$. \square

Corollary 8.6. *Let M be a finitely generated left D -module satisfying $\text{hom}_D(M, D) = 0$. Then, M is a torsion left D -module.*

Proof. If $M^* = \text{hom}_D(M, D) = 0$, then $M^{**} = \text{hom}_D(M^*, D) = 0$. Then, using the exact sequence (22), we obtain that $\text{ext}_D^1(N, D) = \ker \varepsilon_M = M$. Finally, using Theorem 8.3, we obtain that $t(M) = \text{ext}_D^1(N, D) = M$, i.e., M is a torsion left D -module. \square

Theorem 8.7. *Let us suppose that $\text{rgld } D = n < +\infty$ and let M be a left D -module defined by the finite presentation (15) and N its transposed module defined by the finite presentation (16). Then, M is a projective left D -module iff $\text{ext}_D^i(N, D) = 0$, $i = 1, \dots, \text{rgld } D$.*

Proof. \Rightarrow Let us suppose that M is a projective left D -module. In particular, M is a reflexive left D -module, and thus, by Theorem 8.5, we have $\text{ext}_D^i(N, D) = 0$, $i = 1, 2$.

Let us notice that from the exact sequence (16), we deduce [4, 33]:

$$\text{ext}_D^{i+2}(N, D) \cong \text{ext}_D^i(M^*, D), \quad i \geq 1.$$

Now, using the fact that M is a projective left D -module, we obtain that M^* is a projective right D -module. Therefore, we have $\text{ext}_D^i(M^*, D) = 0$, $i \geq 1$ [4, 33] which implies that $\text{ext}_D^i(N, D) = 0$, $i \geq 3$, and finally proves the first implication.

\Leftarrow Let us suppose that $\text{ext}_D^i(N, D) = 0$, $i = 1, \dots, \text{rgld } D$. Let us consider a projective resolution of length $\text{rgld } D$ of the right D -module N :

$$0 \longleftarrow N \longleftarrow P_0 \xleftarrow{r_1} P_1 \xleftarrow{r_2} P_2 \xleftarrow{r_3} \dots \xleftarrow{r_{\text{rgld } D}} P_{\text{rgld } D} \longleftarrow 0. \quad (26)$$

Dualizing (26) and using the fact that $\text{ext}_D^i(N, D) = 0$, $i = 1, \dots, \text{rgld } D$, we obtain that the following complex

$$0 \longrightarrow N^* \longrightarrow P_0^* \xrightarrow{r_1^*} P_1^* \xrightarrow{r_2^*} P_2^* \xrightarrow{r_3^*} \dots \xrightarrow{r_{\text{rgld } D}^*} P_{\text{rgld } D}^* \longrightarrow 0 \quad (27)$$

is an exact sequence. The dual of a projective D -module is also a projective D -module [4, 33], and thus, P_i^* is a projective left D -module for $i = 0, \dots, \text{rgld } D$. Moreover, the exact sequence (27) ends with a projective left D -module $P_{\text{rgld } D}^*$, and thus, (27) is a split exact sequence (see Proposition 3.8).

Therefore, by induction, we deduce that $\text{im } r_i^*$ is a projective left D -module for $i = 1, \dots, \text{rgld } D$, and thus, we obtain the split exact sequence

$$0 \longrightarrow N^* \longrightarrow P_0^* \longrightarrow \text{im } r_1^* \longrightarrow 0,$$

which shows that $P_0^* \cong N^* \oplus \text{im } r_1^*$, i.e., N^* is a projective left D -module. Hence, the right D -module N^{**} is also projective. Dualizing again the split exact sequence (27) and using the fact that the P_i are projective D -modules, and thus, reflexive, namely $P_i^{**} \cong P_i$, we obtain the split exact sequence

$$0 \longleftarrow N^{**} \longleftarrow P_0 \xleftarrow{r_1} P_1 \xleftarrow{r_2} P_2 \xleftarrow{r_3} \dots \xleftarrow{r_{\text{rgld } D}} P_{\text{rgld } D} \longleftarrow 0,$$

from which we deduce that $N \cong N^{**}$, and thus, N is a projective right D -module. The exact sequence (16) ends with the projective right D -module N , and thus, (16) is a split exact sequence (see Proposition 3.8). Thus, we deduce that M^* is a projective right D -module, which implies that M^{**} is a projective left D -module. Finally, using the fact that $\text{ext}_D^i(N, D) = 0$, $i = 1, 2$, by Theorem 8.5, we obtain that $M \cong M^{**}$, and thus, M is a projective left D -module. \square

Corollary 8.8. *Let $M = D^{1 \times p} / D^{1 \times q} R$ be a left D -module and $\tilde{N} = D^{1 \times q} / D^{1 \times p} \theta(R)$ the transposed module of M . Then, we have the following equivalences:*

1. *The system $Ry = 0$ is parametrizable iff $t(M) \cong \text{ext}_D^1(N, D) = 0$. Then, the matrix L_2 in $\text{EXT}_1(R)$ is a parametrization of the system $Ry = 0$.*
2. *If R has full row rank, namely $S(D^{1 \times q} R) = 0$, then the following assertions are equivalent:*
 - (a) *M is a projective left D -module,*
 - (b) *$\exists S \in D^{p \times q} : RS = I_q$,*
 - (c) *$N = \text{ext}_D^1(M, D) = 0$.*

Proof. 1. \Rightarrow Let us suppose that $Ry = 0$ is parametrizable. Then there exists $R_{-1} \in D^{p \times m}$ such that $M = D^{1 \times p} / D^{1 \times q} R \cong D^{1 \times p} R_{-1} \subseteq D^{1 \times m}$. Therefore, the left D -module M is isomorphic to a left submodule $\phi(M)$ of $D^{1 \times m}$, where ϕ is the isomorphism between M and $D^{1 \times p} R_{-1}$. Let us suppose that there exists a non-zero torsion element $z \in M$ satisfying $dz = 0$, where $0 \neq d \in D$. Then, we have $\phi(dz) = 0$, and thus, using the fact that ϕ is a D -morphism, then we obtain $d\phi(z) = 0$, i.e., $\phi(z)$ is a torsion element of $D^{1 \times m}$. But, $D^{1 \times m}$ is a free left D -module, and thus, $t(D^{1 \times m}) = 0$, which proves that $t(M) \cong \text{ext}_D^1(N, D) = 0$ (or, equivalently, if $\{e_i\}_{1 \leq i \leq m}$ is a basis of $D^{1 \times m}$, then $z = \sum_{i=1}^m a_i e_i$, where $a_i \in D$, and thus, $dz = 0 \Rightarrow da_i = 0$, $i = 1, \dots, m$, because $\{e_i\}_{1 \leq i \leq m}$ is a basis, which proves that $a_i = 0$, $i = 1, \dots, m$, i.e., $z = 0$, since $0 \neq d \in D$ and D is an integral domain).

1. \Leftarrow Let us consider the following free resolution of \tilde{N} :

$$0 \longleftarrow \tilde{N} \longleftarrow D^{1 \times q} \xleftarrow{\theta(R)} D^{1 \times p} \xleftarrow{\theta(R_{-1})} D^{1 \times m}.$$

Using the fact that $t(M) \cong \text{ext}_D^1(N, D) = 0$, we have the following exact sequence:

$$D^{1 \times q} \xrightarrow{\cdot R} D^{1 \times p} \xrightarrow{\cdot R_{-1}} D^{1 \times m}.$$

Therefore, we have $M = D^{1 \times p} / D^{1 \times q} R = \text{coker } \cdot R \cong \text{im } \cdot R_{-1} \cong D^{1 \times p} R_{-1}$, i.e., $Ry = 0$ is parametrized by means of R_{-1} .

2. Using the fact that M is defined by a full row rank matrix, we have the exact sequence:

$$0 \longrightarrow D^{1 \times q} \xrightarrow{\cdot R} D^{1 \times p} \longrightarrow M \longrightarrow 0. \quad (28)$$

Dualizing this exact sequence, we obtain the following exact sequence

$$0 \longleftarrow N \longleftarrow D^q \xleftarrow{\cdot R} D^p \longleftarrow M^* \longleftarrow 0, \quad (29)$$

where we easily check that $N = \text{ext}_D^1(M, D)$.

$a \Rightarrow b$. Let us suppose that M is a projective left D -module. Therefore, (28) is a split exact sequence because it ends in a projective left D -module (see Proposition 3.8), i.e., there exists $S \in D^{p \times q}$ such that $RS = I_q$.

$b \Rightarrow c$. Let us suppose that there exists $S \in D^{p \times q}$ such that $RS = I_q$. Hence, for all $\lambda \in D^q$, we have $R\mu = \lambda$ with $\mu = S\lambda \in D^p$. Therefore, the D -morphism $R : D^p \rightarrow D^q$ is surjective, and thus, $N = \text{coker } R = 0$.

$c \Rightarrow a$. Let us suppose that $N = 0$. Then, (29) ends in a free D -module, and thus, (29) splits (see Proposition 3.8), i.e., there exists $S \in D^{p \times q}$ such that $RS = I_q$. Therefore, (28) is also a split exact sequence, and thus, we have $D^{1 \times p} \cong D^{1 \times q} \oplus M$, which proves that M is a projective left D -module. \square

Example 8.9. Let us check whether or not the differential time-delay system defined by (4) is controllable or, equivalently, parametrizable. By Proposition 4.2, we know that (4) is controllable iff the D_h -module $M = D_h^{1 \times 4} / D_h^{1 \times 3} R$ is torsion-free, where R is defined by (5). By Theorem 8.3, this is equivalent to check $\text{ext}_{D_h}^1(N, D_h) = 0$, where $N = D_h^{1 \times 3} / D_h^{1 \times 4} R^T$ (see 1 of Example 6.5). Therefore, system (4) is controllable and, using 1 of Corollary 8.8, we deduce that a parametrization of (4) is given by the matrix R_{-1} defined in Example 5.5:

$$\begin{cases} (\omega^2 k a \delta_h) z(t) = x_1(t), \\ (\omega^2 \partial + \omega^2 a) z(t) = x_2(t), \\ (\omega^2 \partial^2 + \omega^2 a \partial) z(t) = x_3(t), \\ (\partial^3 + (2\zeta\omega + a)\partial^2 + (\omega^2 + 2a\zeta\omega)\partial + a\omega^2) z(t) = u(t), \end{cases} \Rightarrow (4). \quad (30)$$

Finally, the fact that $\text{ext}_{D_h}^2(N, D_h) \neq 0$ implies that $M = D_h^{1 \times 4} / D_h^{1 \times 3} R$ is not a projective, and thus, is not a free D_h -module (see 2 of Theorem 3.6). The obstruction for M to be free is given by (14): the fact that system (14) is not equivalent to $y = 0$ means that it is not possible to express z in terms of a D_h -linear combination of x_1, x_2, x_3 and u . Therefore, (4) is not a flat differential time-delay system.

9 π -freeness, minimal parametrizations and flatness

9.1 Left-Inverses & π -freeness

In order to check the flatness of a linear control system, we need to know whether or not the associated D -module is projective, and thus, by Theorem 8.7, we need to compute $\text{ext}_D^i(N, D)$ for $i = 1, \dots, \text{rgld } D$. However, if the system is defined by a full row rank matrix, then 2 of Corollary 8.8 gives a more economic way to check projectiveness. We need to check if R admits a right-inverse S .

Algorithm 9.1.

Input: An Ore algebra D satisfying (2) and a matrix $R \in D^{q \times p}$.

Output: A matrix $S \in D^{p \times q}$ satisfying $SR = I_p$ if it exists and [] otherwise.

LEFT-INVERSE(R)

Introduce the indeterminates $\lambda_j, j = 1, \dots, p$ and $\mu_i, i = 1, \dots, q$, over D .

$P \leftarrow \{\sum_{j=1}^p R_{ij} \lambda_j - \mu_i \mid i = 1, \dots, q\}$,

Compute the Gröbner basis G of P in $\bigoplus_{i=1}^p D \lambda_i \oplus \bigoplus_{i=1}^q D \mu_i$

w.r.t. an order which eliminates the λ_i 's.

Remove from G the elements which do not contain any λ_i

and call G' this new set.

Write G' in the form $Q_1 \cdot (\lambda_1 : \dots : \lambda_p)^T - Q_2 \cdot (\mu_1 : \dots : \mu_q)^T$.

If Q_1 is invertible in D , then return $S = Q_1^{-1} Q_2 \in D^{p \times q}$, else return [].

Now, we can compute a right-inverse $S \in D^{p \times q}$ of $R \in D^{q \times p}$ ($RS = I_q$), when such an inverse exists, by doing $\text{RIGHT-INVERSE}(R) = \theta(\text{LEFT-INVERSE}(\theta(R)))$. Therefore, if $R \in D^{q \times p}$ has full row rank, by 2 of Corollary 8.8, the left D -module $M = D^{1 \times p} / D^{1 \times q} R$ is projective iff $\text{RIGHT-INVERSE}(R) \neq []$.

Example 9.2. Let us consider again the differential time-delay system defined by (4). Applying Algorithm 9.1 to $\theta(R) = R^T$, where R is defined by (5), we are led to the Gröbner basis G defined in Example 5.5. We easily check that G does not contain any relation of the form $\lambda_i - \sum_{j=1}^4 S_{ij} \mu_j$, where $S_{ij} \in D_h$, for $i = 1, \dots, 3$. Therefore, $M = D_h^{1 \times 4} / D_h^{1 \times 3} R$ is not a projective D_h -module, and thus, (4) is not a flat system [20] (see also Example 8.9).

If $D = k[x_1, \dots, x_n]$ is a commutative polynomial ring over a field k , then we can study the obstructions for a system to be free (i.e., projective by the Quillen-Suslin theorem stated in Theorem 3.6). In this case, they are given by polynomials containing a certain number of variables x_i which depends on the properties of the corresponding D -module M .

Definition 9.3. Let $D = k[x_1, \dots, x_n]$, $R \in D^{q \times p}$ be a full row rank matrix and let us define the D -module $M = D^{1 \times p} / D^{1 \times q} R$. Then, let us define:

$$i(M) = \min_{i \geq 1} \{i - 1 \mid \text{ext}_D^i(N, D) \neq 0\} \in \{0, \dots, n - 1, +\infty\}.$$

$i(M)$ is called the *torsion-free degree* of M .

Let us notice that the torsion-free degree of the module $M = D^{1 \times p} / D^{1 \times q} R$ over $D = k[x_1, \dots, x_n]$ measures how far M is from projectivity. In particular, $i(M) = 0$ means that M has some torsion elements, whereas $i(M) = 1$ means that M is a torsion-free but not reflexive D -module, ..., and $i(M) = +\infty$ means that for all $i \geq 1$, we have $\text{ext}_D^i(N, D) = 0$, i.e., M is a projective D -module.

Proposition 9.4. [31] Let $D = k[x_1, \dots, x_n]$, $R \in D^{q \times p}$ be a full row rank matrix and the D -modules $M = D^{1 \times p} / D^{1 \times q} R$ and $N = D^{1 \times q} / D^{1 \times p} R^T$. For every partition of $X = \{x_1, \dots, x_n\}$ into two disjoint subsets X_1 and X_2 with respectively $n - i(M)$ elements and $i(M)$ elements, there exists

$$\begin{cases} \pi_{n-i(M)} \in k[X_1], & \text{if } 0 \leq i(M) \leq n - 1, \\ \pi_{n-i(M)} \in k, & \text{if } i(M) = +\infty, \end{cases}$$

such that the module over $D_{\pi_{n-i(M)}} = \{d/a \mid d \in D, a = \pi_{n-i(M)}^m, m \in \mathbb{Z}_{\geq 0}\}$

$$D_{\pi_{n-i(M)}} \otimes_D M = \left\{ m/a \mid m \in M, a = \pi_{n-i(M)}^m, m \in \mathbb{Z}_{\geq 0} \right\}$$

is free. Moreover, there exist $R_{-1} \in D^{p \times (p-q)}$, $T \in D^{p \times q}$, $T_{-1} \in D^{(p-q) \times p}$ and $\nu \in \mathbb{Z}_{\geq 0}$ such that:

$$(T : R_{-1}) \begin{pmatrix} R \\ T_{-1} \end{pmatrix} = \pi_{n-i(M)}^\nu I_p, \quad \begin{pmatrix} R \\ T_{-1} \end{pmatrix} (T : R_{-1}) = \pi_{n-i(M)}^\nu I_p. \quad (31)$$

Proof. If $i(M) = +\infty$, then, using 2 of Proposition 5.6, we have:

$$\text{ext}_D^i(N, D) = 0, \quad i = 1, \dots, \text{gld } D = n.$$

So, by Proposition 8.7, M is a projective D -module, and thus, by 2 of Theorem 3.6, M is a free D -module. Hence, we can choose $\pi_{n-\infty} = 1 \in k \setminus 0$ and we have $D_{\pi_{n-\infty}} = D$. Using the fact that R has full row rank, then we have the following exact sequence:

$$0 \longrightarrow D^{1 \times q} \xrightarrow{\cdot R} D^{1 \times p} \longrightarrow M \longrightarrow 0. \quad (32)$$

We apply the functor $K \otimes_D \cdot$ to the exact sequence (32), where $K = Q(D)$ is the quotient field of D . Using the fact that K is a flat D -module, then we obtain the exact sequence

$$0 \longrightarrow K^{1 \times q} \xrightarrow{\cdot R} K^{1 \times p} \longrightarrow K \otimes M \longrightarrow 0,$$

which shows that $\text{rank}_D(M) = \dim_K(K \otimes_D M) = \dim_K K^{1 \times p} - \dim_K K^{1 \times q} = p - q$. Hence, since M is free, therefore isomorphic to D^{p-q} , we obtain the split exact sequence

$$0 \longrightarrow D^{1 \times q} \begin{array}{c} \xrightarrow{\cdot R} \\ \xleftarrow{\cdot T} \end{array} D^{1 \times p} \begin{array}{c} \xrightarrow{\cdot R_{-1}} \\ \xleftarrow{\cdot T_{-1}} \end{array} D^{1 \times (p-q)} \longrightarrow 0,$$

and thus, identities (31).

Now, let us suppose that we have $0 \leq i(M) \leq n - 1$. Then, we have:

$$\text{ext}_D^j(N, D) = 0, \quad 0 \leq j \leq i(M).$$

Let us consider the multiplicatively closed subset $S = k[X_1] \setminus \{0\}$ of D and $S^{-1}D = k(X_1)[X_2]$. By 2 of Proposition 5.6, we have $\text{gl}d S^{-1}D = i(M)$, and thus, for the $S^{-1}D$ -module $S^{-1}D \otimes_D N$, we have:

$$\forall j \geq i(M) + 1, \quad \text{ext}_{S^{-1}D}^j(S^{-1}D \otimes_D N, S^{-1}D) = 0.$$

Then, by Lemma 3.9, we conclude that:

$$\forall j \geq i(M) + 1, \quad S^{-1}D \otimes_D \text{ext}_D^j(N, D) \cong \text{ext}_{S^{-1}D}^j(S^{-1}D \otimes_D N, S^{-1}D) = 0,$$

i.e., $S^{-1}D \otimes_D \text{ext}_D^j(N, D) = 0$, for all $j \geq i(M) + 1$.

Let us consider $i(M) + 1 \leq j \leq n$. One can prove that a non-zero $\text{ext}_D^j(N, D)$ is a torsion D -module for $j \geq 1$ (see [25, 29] for more details). So, if $\text{ext}_D^j(N, D) \neq 0$, then:

$$\text{ann}(\text{ext}_D^j(N, D)) = \{P \in D \mid \forall m \in \text{ext}_D^j(N, D), Pm = 0\} \neq 0.$$

If $i_{S^{-1}D} : \text{ext}_D^j(N, D) \rightarrow S^{-1}D \otimes \text{ext}_D^j(N, D)$ denotes the canonical map (see (20) for more details), then, for $0 \neq z \in \text{ext}_D^j(N, D)$, we have $i_{S^{-1}D}(z) = 0$ iff $\{P \in D \mid Pz = 0\} \cap S \neq \emptyset$. Therefore, using the fact that $S^{-1}D \otimes \text{ext}_D^j(N, D) = 0$, we obtain:

$$\text{ann}(\text{ext}_D^j(N, D)) \cap (k[X_1] \setminus \{0\}) \neq \emptyset.$$

For $i(M) + 1 \leq j \leq n$, if $\text{ext}_D^j(N, D) \neq 0$, we take any $p_j \in \text{ann}(\text{ext}_D^j(N, D)) \cap (k[X_1] \setminus \{0\})$, else, we take $p_j = 1$. Let us denote by $\pi_{n-i(M)}$ the product of the p_j for $i(M) + 1 \leq j \leq n$. By construction, we have $\pi_{n-i(M)} \in k[X_1]$ and:

$$\pi_{n-i(M)} \text{ext}_D^j(N, D) = 0, \quad 0 \leq j \leq n.$$

If we denote by $S_{\pi_{n-i(M)}} = \{1, \pi_{n-i(M)}, \pi_{n-i(M)}^2, \dots\}$ the multiplicatively closed subset of D defined by $\pi_{n-i(M)}$ and $D_{\pi_{n-i(M)}} \triangleq S_{\pi_{n-i(M)}}^{-1}D = \{d/a \mid d \in D, a = (\pi_{n-i(M)})^m, m \in \mathbb{Z}_{\geq 0}\}$, then, using Lemma 3.9, from $D_{\pi_{n-i(M)}} \otimes_D \text{ext}_D^j(N, D) = 0$, $0 \leq j \leq n$, we conclude that:

$$\text{ext}_{D_{\pi_{n-i(M)}}}^j(D_{\pi_{n-i(M)}} \otimes_D N, D_{\pi_{n-i(M)}}) = 0, \quad 0 \leq j \leq n.$$

Since the transposed module of $M' \triangleq D_{\pi_{n-i(M)}} \otimes_D M$ is $D_{\pi_{n-i(M)}} \otimes_D N$, by Proposition 8.7, it follows that M' is a projective $D_{\pi_{n-i(M)}}$ -module, and thus, by 2 of Theorem 3.6, M' is a free $D_{\pi_{n-i(M)}}$ -module.

Now, using the fact that M' is a free $D_{\pi_{n-i(M)}}$ -module of rank $p - q$, there exist $R'_{-1} \in D_{\pi_{n-i(M)}}^{p \times (p-q)}$, $T' \in D_{\pi_{n-i(M)}}^{p \times q}$ and $T'_{-1} \in D_{\pi_{n-i(M)}}^{(p-q) \times p}$ such that we have the following split exact sequence

$$0 \longrightarrow D_{\pi_{n-i(M)}}^{1 \times q} \xrightarrow{\cdot R} D_{\pi_{n-i(M)}}^{1 \times p} \xrightarrow{\cdot R'_{-1}} D_{\pi_{n-i(M)}}^{1 \times (p-q)} \longrightarrow 0,$$

$$\xleftarrow{\cdot T'} \quad \xleftarrow{\cdot T'_{-1}}$$

or, equivalently, the following identities:

$$(T' : R'_{-1}) \begin{pmatrix} R \\ T'_{-1} \end{pmatrix} = I_p, \quad \begin{pmatrix} R \\ T'_{-1} \end{pmatrix} (T' : R'_{-1}) = I_p.$$

Collecting common denominators yields matrices $R_{-1} \in D^{p \times (p-q)}$, $T \in D^{p \times q}$, $T_{-1} \in D^{(p-q) \times p}$ and $\nu \in \mathbb{Z}_{\geq 0}$ as asserted in the theorem. \square

In order to compute such a polynomial $\pi_{n-i(M)}$, we can follow π -POLYNOMIAL [31].

Algorithm 9.5.

Input: A commutative polynomial ring $D = k[x_1, \dots, x_n]$, where k is a field, a left D -module $M = D^{1 \times p} / D^{1 \times q} R$, $i(M)$ the torsion-free degree of M , a partition of $X = \{x_1, \dots, x_n\}$ into disjoint subsets X_1 and X_2 with respectively $n - i(M)$ elements and $i(M)$ elements.

Output: An ideal J of $k[X_1]$ such that any element $\pi \in J$ satisfies that $D_\pi \otimes_D M$ is a free D_π -module.

π -POLYNOMIAL(R, X_1)

$R_1 \leftarrow R.$

for $i = i(M) + 1, \dots, n$ **do**

$L_i = [L_{i0}, L_{i1}, L_{i2}] \leftarrow \text{EXT1}(R_i).$

Introduce the indeterminates $\mu_j, j = 1, \dots, \text{rowdim}(L_{i1})$ over $D.$

$P_{ij} \leftarrow \{d \in D \mid d \cdot \mu_j \in L_{i0}\}, \quad j = 1, \dots, \text{rowdim}(L_{i1}).$

$R_{i+1} \leftarrow \text{SYZYGIES}(R_i).$

endfor

$I \leftarrow \bigcap_{i,j} \langle P_{ij} \rangle.$

$J \leftarrow I \cap k[X_1].$

In π -POLYNOMIAL, the set $\{d \in D \mid d \cdot \mu_j \in L_{i0}\}$ is obtained in the step QUOTIENT of EXT1(R_i). See Remark 7.6 for more details. Moreover, in the last step of π -POLYNOMIAL, the intersection of ideals of Ore algebras can be computed by means of elimination algorithms (see [2] and Example 2.15).

Example 9.6. In Examples 8.9 and 9.2, we proved that the linear differential time-delay system defined by (4) is not flat, i.e., the associated D_h -module $M = D_h^{1 \times 4} / D_h^{1 \times 3} R$ is not free. Let us find a polynomial $\pi \in \mathbb{R}(a, k, \zeta, \omega)[\delta_h; \sigma_2, \delta_2]$ such that the $(D_h)_\pi$ -module $(D_h)_\pi \otimes_{D_h} M$ is free. In Example 7.4, we saw that $\text{ext}_{D_h}^1(N, D_h) = 0$ and $\text{ext}_{D_h}^2(N, D_h) \neq 0$. Therefore, the torsion-free degree $i(M)$ of M is 1. Applying Algorithm 9.5 and using (14), we find that:

$$I = (\omega^2 k a \delta_h, \omega^2 \partial + \omega^2 a, \omega^2 \partial^2 + \omega^2 a \partial, \partial^3 + (2 \zeta \omega + a) \partial^2 + (\omega^2 + 2 a \zeta \omega) + a \omega^2).$$

Thus, we have $I \cap \mathbb{R}(a, k, \zeta, \omega)[\delta_h; \sigma_2, \delta_2] = (\delta_h)$, which shows that (4) is δ_h -free [20].

We refer to [31] for an extension of Proposition 9.4 to none full row rank matrices.

9.2 Minimal parametrizations and flatness

The next theorem generalizes a result of [26] obtained for systems of partial differential equations. We assume that D is a left/right noetherian integral domain.

Theorem 9.7. [30] *Let M be a torsion-free left D -module defined by the finite presentation (15). Then, there always exists a left D -morphism $d'_0 : F_0 \longrightarrow F'_{-1}$, where F'_{-1} is a finitely generated free left D -module, such that we have the following exact sequence*

$$F_1 \xrightarrow{d_1} F_0 \xrightarrow{d'_0} F'_{-1},$$

and $M'_{-1} = \text{coker } d'_0$ is either 0 or a torsion left D -module. Such a morphism d'_0 is then called a minimal parametrization of M .

Proof. Let us consider the beginning of a free resolution of the transposed right D -module N of M , i.e., we have the following exact sequence

$$0 \longleftarrow N \longleftarrow F_1^* \xleftarrow{d_1^*} F_0^* \xleftarrow{d_0^*} F_{-1}^* \longleftarrow L \longleftarrow 0,$$

where F_{-1}^* is a finitely generated free right D -module and $L = \ker d_0^*$.

If we have $L = 0$, dualizing the previous exact sequence and using the fact that M is a torsion-free left D -module, and thus, $\text{ext}_D^1(N, D) = 0$ by Theorem 8.3, then the following complex

$$F_1 \xrightarrow{d_1} F_0 \xrightarrow{d_0} F_{-1} \longrightarrow 0$$

is exact in F_0 . Then, we have $\text{ext}_D^2(N, D) = \text{coker } d_0$. Hence, $\text{ext}_D^2(N, D)$ is either 0 if M is a reflexive left D -module (and thus, $M \cong \text{im } d_0 = F_{-1}$ is a free left D -module) or, by Corollary 8.6, $\text{ext}_D^2(N, D)$ is a non-zero torsion left D -module because we have $\text{hom}_D(\text{ext}_D^2(N, D), D) = 0$. Hence, $d'_0 = d_0$ and $F'_0 = F_0$ satisfy the theorem and d_0 is a minimal parametrization of M .

Now, let us suppose that $L \neq 0$. Then, we have the following exact sequence

$$0 \longleftarrow \text{im } d_0^* \longleftarrow F_{-1}^* \longleftarrow L \longleftarrow 0,$$

from which we deduce that:

$$\text{rank}_D \text{im } d_0^* = \text{rank}_D F_{-1}^* - \text{rank}_D L \geq 1. \quad (33)$$

Indeed, if $\text{rank}_D \text{im } d_0^* = \dim_K(K \otimes_D \text{im } d_0^*) = 0$, then $K \otimes_D \text{im } d_0^* = 0$, i.e., $\text{im } d_0^*$ is a torsion right D -module. But, $\text{im } d_0^* \subseteq F_0^*$ and F_0^* is a free, and thus, torsion-free right D -module. Hence, $\text{im } d_0^* = 0$, and thus, $F_{-1}^* = 0$ which contradicts the hypothesis that $L \neq 0$. Hence, we have $l' \triangleq \text{rank}_D \text{im } d_0^* \geq 1$.

From the matrix R_0 which corresponds to d_0^* in the canonical basis of F_{-1}^* and F_0^* , let us extract a $(\text{rank}_D F_0^* \times l')$ -submatrix R'_0 composed by D -linear independent columns of R_0 , which, in turn, defines a right D -morphism $d_0'^* : F_{-1}' \rightarrow F_0^*$ in the canonical basis, where F_{-1}' is a free right D -module of rank l' . Using the fact that R'_0 has full column rank, then $d_0'^*$ is injective. Thus, we have the following commutative exact diagram

$$\begin{array}{ccccccc}
& & & & 0 & & \\
& & & & \uparrow & & \\
& & & & \text{coker } \phi & & \\
& & & & \uparrow & & \\
& & & & \uparrow & & \\
0 & \longleftarrow & N_1 & \longleftarrow & F_0^* & \xleftarrow{d_0^*} & F_{-1}^* & \longleftarrow & L & \longleftarrow & 0 \\
& & & & \parallel & & \uparrow \phi & & & & \\
0 & \longleftarrow & N'_1 & \longleftarrow & F_0^* & \xleftarrow{d_0'^*} & F_{-1}' & \longleftarrow & 0, & & \\
& & & & \uparrow & & \uparrow & & & & \\
& & & & 0 & & 0 & & & &
\end{array} \tag{34}$$

where $d_0'^* = d_0^* \circ \phi$, $N_1 = \text{coker } d_{-1}^*$ and $N'_1 = \text{coker } d_{-1}'$. Using the snake lemma [4, 33], we obtain the following exact sequence $0 \longleftarrow N_1 \xleftarrow{\psi} N'_1 \longleftarrow \text{coker } \phi \longleftarrow L \longleftarrow 0$. Using (33), we have:

$$\begin{aligned}
\text{rank}_D N_1 - \text{rank}_D N'_1 &= \text{rank}_D L - \text{rank}_D \text{coker } \phi = \text{rank}_D L - \text{rank}_D F_{-1}^* + \text{rank}_D F_{-1}' \\
&= -\text{rank}_D \text{im } d_0^* + \text{rank}_D F_{-1}' = 0.
\end{aligned}$$

Therefore, we have $\text{rank}_D N_1 = \text{rank}_D N'_1$, and thus, $\text{rank}_D \ker \psi = 0$ because we have the exact sequence $0 \longleftarrow N_1 \xleftarrow{\psi} N'_1 \longleftarrow \ker \psi \longleftarrow 0$. Hence, $\ker \psi$ is a torsion right D -module. This fact implies that $\text{hom}_D(\ker \psi, D) = 0$ and, dualizing the previous exact sequence, we have $N_1^* \triangleq \text{hom}_D(N_1, D) = N_1'^* \triangleq \text{hom}_D(N'_1, D)$. Dualizing the commutative exact diagram (34), we obtain the following commutative exact diagram:

$$\begin{array}{ccccccc}
& & & & 0 & & 0 \\
& & & & \downarrow & & \downarrow \\
0 & \longrightarrow & N_1^* & \longrightarrow & F_0 & \xrightarrow{d_0} & F_{-1} \\
& & \downarrow \psi^* & & \parallel & & \downarrow \phi^* \\
0 & \longrightarrow & N_1'^* & \longrightarrow & F_0 & \xrightarrow{d_0'} & F_{-1}' \\
& & \downarrow & & \downarrow & & \\
& & 0 & & 0 & &
\end{array}$$

Therefore, we have $\ker d_0 = N_1^*$ and $\ker d_0' = N_1'^*$. Hence, the defect of exactness of the following complex

$$F_1 \xrightarrow{d_1} F_0 \xrightarrow{d_0'} F_{-1}' \tag{35}$$

at F_0 is defined by $H(F_0) = \ker d_0' / \text{im } d_1 = \ker d_0' / \ker d_0$, because $\ker d_0 = \text{im } d_1$ as we have $\text{ext}_D^1(N, D) = 0$. Finally, we obtain that $H(F_0) = N_1^* / N_1'^* = 0$ because we have $N_1^* = N_1'^*$. Thus, (35) is an exact sequence, and thus, d_0' is a parametrization of M . Finally, we have $\text{hom}_D(\text{coker } d_0', D) = \ker d_0'^* = 0$, and thus, by Corollary 8.6, $\text{coker } d_0'$ is a torsion left D -module, which proves the result. \square

Algorithm 9.8.

Input: An Ore algebra D satisfying (2) with an involution θ ,
a torsion-free left D -module $M = D^{1 \times p} / D^{1 \times q} R$.

Output: A minimal parametrization $R'_{-1} \in D^{p \times m}$ of M .

MINIMAL-PARAMETRIZATION (R)

$L \leftarrow \text{SYZYGIES}(\theta(R))$.

$m \leftarrow \text{rank}_D(L)$.

Select m D -linearly independent rows of L and
form a $p \times m$ -matrix L' with them.

$R'_{-1} \leftarrow \theta(L')$.

Example 9.9. Let us consider the first set of Maxwell equations [15], namely

$$\begin{cases} \frac{\partial \vec{B}}{\partial t} + \vec{\nabla} \wedge \vec{E} = 0, \\ \vec{\nabla} \cdot \vec{B} = 0, \end{cases} \quad (36)$$

where \vec{B} (resp. \vec{E}) denotes the magnetic (resp. electric) field. In electromagnetism, it is well-known that (36) is parametrized by

$$\begin{cases} \vec{\nabla} \wedge \vec{A} = \vec{B}, \\ -\nabla V - \frac{\partial \vec{A}}{\partial t} = \vec{E}, \end{cases} \quad (37)$$

where (\vec{A}, V) is called *quadri-potential* [15]. In terms of module theory, this result means that the D -module $M = D^{1 \times 6} / D^{1 \times 4} R$ is torsion-free, where $D = A_4$ denotes the Weyl algebra (see Example 2.3), $x_4 = t$ the time variable, and R is the matrix of differential operators defining (36), namely:

$$R = \begin{pmatrix} \partial_4 & 0 & 0 & 0 & -\partial_3 & \partial_2 \\ 0 & \partial_4 & 0 & \partial_3 & 0 & -\partial_1 \\ 0 & 0 & \partial_4 & -\partial_2 & \partial_1 & 0 \\ \partial_1 & \partial_2 & \partial_3 & 0 & 0 & 0 \end{pmatrix} \in D^{4 \times 6}.$$

We easily check that a free resolution of the D -module M is defined by

$$0 \longrightarrow D \xrightarrow{\cdot R_2} D^{1 \times 4} \xrightarrow{\cdot R} D^{1 \times 6} \longrightarrow M \longrightarrow 0, \quad (38)$$

where $R_2 = (\partial_1 : \partial_2 : \partial_3 : -\partial_4) \in D^{1 \times 4}$. Therefore, we obtain $\text{rank}_D(M) = 6 - 4 + 1 = 3$ or, in other words, system (36) is defined by $4 - 1 = 3$ D -linearly independent equations in 6 unknowns (\vec{B}, \vec{E}) , and thus, its solutions depend on 3 arbitrary functions of (x_1, x_2, x_3, x_4) . But, the parametrization (37) of the torsion-free D -module M depends on 4 arbitrary potentials, namely (\vec{A}, V) . Hence, by Theorem 9.7, we know that system (36) admits some parametrizations with only 3 arbitrary potentials. Let us compute such parametrizations following Algorithm 9.8. Using Algorithm 5.3, the D -module $N = D^{1 \times 4} / D^{1 \times 6} R^T$ admits the following free resolution

$$0 \longleftarrow N \longleftarrow D^{1 \times 4} \xleftarrow{\cdot R^T} D^{1 \times 6} \xleftarrow{\cdot R_{-1}^T} D^{1 \times 4} \xleftarrow{\cdot R_{-2}^T} D \longleftarrow 0, \quad (39)$$

where:

$$R_{-1}^T = \begin{pmatrix} 0 & -\partial_3 & \partial_2 & \partial_4 & 0 & 0 \\ \partial_3 & 0 & -\partial_1 & 0 & \partial_4 & 0 \\ -\partial_2 & \partial_1 & 0 & 0 & 0 & \partial_4 \\ 0 & 0 & 0 & -\partial_1 & -\partial_2 & -\partial_3 \end{pmatrix}, \quad R_{-2}^T = (\partial_1 : \partial_2 : \partial_3 : \partial_4).$$

Let us point out that

$$R_{-1}^T \begin{pmatrix} \vec{H} \\ -\vec{D} \end{pmatrix} = \begin{pmatrix} \vec{j} \\ \rho \end{pmatrix} \Leftrightarrow \begin{cases} \vec{\nabla} \wedge \vec{H} - \frac{\partial \vec{D}}{\partial t} = \vec{j}, \\ \vec{\nabla} \cdot \vec{D} = \rho, \end{cases}$$

is exactly the second set of Maxwell equations, where \vec{j} denotes the density of current, ρ the density of electric charge, \vec{H} the magnetic induction and \vec{D} the electric induction. Then, the conservation of current is given by:

$$R_{-2}^T \begin{pmatrix} \vec{j} \\ \rho \end{pmatrix} = 0 \Leftrightarrow \frac{\partial \rho}{\partial t} + \vec{\nabla} \cdot \vec{j} = 0.$$

If we denote by $S(R^T)$ the syzygy module of R^T , from the free resolution (39) of N , we obtain that $\text{rank}_D S(R^T) = \text{rank}_D D^{1 \times 4} R_{-1}^T = 4 - 1 = 3$. Hence, if we select 3 different rows of R_{-1}^T and transpose the corresponding matrix, we obtain a parametrization of (36) with only 3 potentials. Hence, we have the following 4 minimal parametrizations of (36) with only 3 arbitrary potentials $\vec{\xi} = (\xi_1 : \xi_2 : \xi_3)^T$:

$$\begin{cases} -\vec{\nabla} \wedge \vec{\xi} = \vec{B}, \\ \frac{\partial \vec{\xi}}{\partial t} = \vec{E}, \end{cases} \quad \begin{cases} \partial_3 \xi_2 = B_1, \\ -\partial_3 \xi_1 = B_2, \\ \partial_2 \xi_1 - \partial_1 \xi_2 = B_3, \\ \partial_4 \xi_1 - \partial_1 \xi_3 = E_1, \\ \partial_4 \xi_2 - \partial_2 \xi_3 = E_2, \\ -\partial_3 \xi_3 = E_3, \end{cases} \quad \begin{cases} -\partial_2 \xi_2 = B_1, \\ -\partial_3 \xi_1 + \partial_1 \xi_2 = B_2, \\ \partial_2 \xi_1 = B_3, \\ \partial_4 \xi_1 - \partial_1 \xi_3 = E_1, \\ -\partial_2 \xi_3 = E_2, \\ \partial_4 \xi_2 - \partial_3 \xi_3 = E_3, \end{cases} \quad \begin{cases} \partial_3 \xi_1 - \partial_2 \xi_2 = B_1, \\ \partial_1 \xi_2 = B_2, \\ -\partial_1 \xi_1 = B_3, \\ -\partial_1 \xi_3 = E_1, \\ \partial_4 \xi_1 - \partial_2 \xi_3 = E_2, \\ \partial_4 \xi_2 - \partial_3 \xi_3 = E_3. \end{cases}$$

To finish, let us give a new result which will allow us to compute some bases of a π -free linear control system.

Proposition 9.10. *Let $D = k[x_1, \dots, x_n]$ be a commutative polynomial ring over a field k and $M = D^{1 \times p}/D^{1 \times q} R$ be a torsion-free D -module. By Theorem 9.7, there exists a minimal parametrization $R_{-1} \in D^{p \times m}$ of M , i.e., a parametrization R_{-1} of M such that $L = D^{1 \times m}/D^{1 \times p} R_{-1}$ is a torsion D -module. Then, for all $0 \neq \pi \in \text{ann}(L) = \{P \in D \mid \forall l \in L : Pl = 0\}$, the D_π -module $D_\pi \otimes_D M$ is free. In particular, there exists $S_{-1} \in D_\pi^{m \times p}$ such that $S_{-1} R_{-1} = I_m$ and, with the notations of Section 3, $z = S_{-1} y$ is a basis of the free D_π -module $D_\pi \otimes_D M$ satisfying $Ry = 0 \Leftrightarrow y = R_{-1} z$.*

Proof. By hypothesis, we have the following exact sequence:

$$D^{1 \times q} \xrightarrow{\cdot R} D^{1 \times p} \xrightarrow{\cdot R_{-1}} D^{1 \times m} \longrightarrow L \longrightarrow 0. \quad (40)$$

Moreover, the fact that the D -module L is torsion implies that $\text{ann}(L) \neq 0$. If $0 \neq \pi \in \text{ann}(L)$, then, using the fact that D_π is a flat D -module [33], then, by applying the right exact functor $D_\pi \otimes_D \cdot$ to the exact sequence (40), we obtain the following exact sequence:

$$D_\pi^{1 \times q} \xrightarrow{\cdot R} D_\pi^{1 \times p} \xrightarrow{\cdot R_{-1}} D_\pi^{1 \times m} \longrightarrow D_\pi \otimes_D L \longrightarrow 0. \quad (41)$$

But, by definition of π , we have $D_\pi \otimes_D L = 0$. Thus, we have $D_\pi \otimes_D M = D_\pi^{1 \times p}/D_\pi^{1 \times q} R \cong D_\pi^{1 \times m}$, i.e., the D_π -module $D_\pi \otimes_D M$ is free of rank m . Moreover, by Proposition 3.8, the exact sequence (41) splits, and thus, there exists $S_{-1} \in D_\pi^{m \times p}$ such that $S_{-1} R_{-1} = I_m$. Finally, in terms of equations, in the D_π -module $D_\pi \otimes_D M$, we have $Ry = 0 \Leftrightarrow y = R_{-1} z$ and $z = (S_{-1} R_{-1}) z = S_{-1} y$. \square

From Proposition 9.10, we easily obtain the following effective algorithm: using Algorithm 9.8, we first compute a minimal parametrization R_{-1} of the torsion-free D -module M and then compute $\text{ann}(D^{1 \times m}/D^{1 \times p} R_{-1})$. After choosing $0 \neq \pi \in \text{ann}(L)$, using Algorithm 9.1 over D_π , we finally compute a left-inverse S_{-1} of R_{-1} , which gives the basis $z = S_{-1} y$ of the D_π -module $D_\pi \otimes_D M$.

Example 9.11. In Example 8.9, we proved that (30) is a parametrization of system (4). We easily check that (30) is also a minimal parametrization of system (4) as the D_h -module $L = D_h/D_h^{1 \times 4} R_{-1} = \text{ext}_{D_h}^2(N, D_h)$ is torsion. From the definition (14) of $\text{ext}_{D_h}^2(N, D_h)$, we obtain $\text{ann}(L) = (\delta_h, \partial + a)$. Hence, if we choose $\pi = \delta_h$, then we easily check that $S_{-1} = (\pi^{-1}/(\omega^2 k a) : 0 : 0 : 0) \in D_\pi^{1 \times 4}$ is a left-inverse of the parametrization R_{-1} defined in Example 5.5. Hence, up to a constant, we obtain that $z = \pi^{-1} x_1$, and thus x_1 , are bases (resp. flat outputs) of the D_π -module $D_\pi \otimes_D M$.

10 Conclusion

We hope that we have convinced the reader that the simultaneous use of module theory, homological algebra, effective algebra and computational methods allows us to study effectively the structural properties of linear multidimensional systems (e.g., systems of ODEs, systems of PDEs, (differential) time-delay systems, discrete systems, convolutional codes with constant or variables coefficients). In particular, in this unified mathematical framework, we presented effective algorithms which check controllability/flatness/ π -freeness... and compute the parametrizations/autonomous elements/flat outputs/ π -polynomials. Certain of these problems were still open for some classes of linear multidimensional systems [36, 37] and, in particular, for linear differential time-delay systems [11, 20].

The Maple package *OreModules*, based on *Mgfun* [6], as well as Maple worksheets containing the explicit examples of the appendix are available at <http://wwwb.math.rwth-aachen.de/OreModules>. We hope that OREMODULES will become in the future a platform for the implementation of different algorithms obtained in the literature of multidimensional linear systems (see e.g., [10, 13, 23, 25, 26, 27, 30, 32, 36, 37] and the references therein).

A Appendix: Examples

In this appendix, we give some Maple worksheets which decide controllability, parametrizability, flatness and π -freeness of some linear time-invariant/time-varying OD systems, differential time-delay systems and systems of PDE with constant or variable coefficients, multidimensional convolutional

codes¹. These results have been obtained using the Maple package *OreModules*² which is crucially based on the library *Mgfun* [6] (e.g. Ore algebras and non-commutative Gröbner bases are developed in *Mgfun*). In these examples, the most time-consuming computation is that of the $\text{ext}_D^1(N, D)$. We give some timings for these operations. All examples were run on a Pentium II, 450 MHz with 512 MB RAM using Maple 8 (*OreModules* is available for Maple V release 5, Maple 6, Maple 8, and Maple 9). Finally, we refer the reader to [9] for a complete description of the package *OreModules* and for more examples using other functions of *OreModules*.

A.1 Two pendula mounted on a cart

The first example that we consider is the linearized time-invariant OD system formed by two pendula mounted on a cart. See for more details Examples 5.2.1 and 5.2.12 in [23].

```
> with(Ore_algebra): with(OreModules):
```

After loading the required Maple packages, the first step is to define the Ore algebra

$$D = \mathbb{R}(m_1, m_2, M, L_1, L_2, g)[t][\partial; \sigma, \delta],$$

where $\sigma = \text{id}_{\mathbb{R}(m_1, m_2, M, L_1, L_2, g)[t]}$ and $\delta = \frac{d}{dt}$. In what follows, this Ore algebra is denoted by *Alg*.

```
> Alg:=DefineOreAlgebra(diff=[Dt,t], polynom={t}, comm={m1,m2,M,L1,L2,g}):
```

In *Alg*, we need to declare the constants m_1, m_2, M, L_1, L_2 , and g which occur in the system. Then, we define the matrix $R \in D^{3 \times 4}$ which corresponds to the system.

```
> R:=evalm([[m1*L1*Dt^2, m2*L2*Dt^2, -1, (M+m1+m2)*Dt^2],
> [m1*L1^2*Dt^2-m1*L1*g, 0, 0, m1*L1*Dt^2],
> [0, m2*L2^2*Dt^2-m2*L2*g, 0, m2*L2*Dt^2]]);
```

$$R := \begin{bmatrix} m_1 L_1 D t^2 & m_2 L_2 D t^2 & -1 & (M + m_1 + m_2) D t^2 \\ m_1 L_1^2 D t^2 - m_1 L_1 g & 0 & 0 & m_1 L_1 D t^2 \\ 0 & m_2 L_2^2 D t^2 - m_2 L_2 g & 0 & m_2 L_2 D t^2 \end{bmatrix}$$

We compute $R_{\text{adj}} = \theta(R) \in D^{4 \times 3}$ using the involution θ defined in 2 of Example 6.3.

```
> R_adj:=Involution(R, Alg);
```

$$R_{\text{adj}} := \begin{bmatrix} m_1 L_1 D t^2 & m_1 L_1^2 D t^2 - m_1 L_1 g & 0 \\ m_2 L_2 D t^2 & 0 & m_2 L_2^2 D t^2 - m_2 L_2 g \\ -1 & 0 & 0 \\ D t^2 M + D t^2 m_1 + D t^2 m_2 & m_1 L_1 D t^2 & m_2 L_2 D t^2 \end{bmatrix}$$

We compute $\text{ext}_D^1(N, D)$, where $N = D^{1 \times 4} / D^{1 \times 3} R_{\text{adj}}$, using the procedure $\text{EXT1}(R_{\text{adj}})$.

```
> st:=time(): Ext1:=Exti(R_adj, Alg, 1): time()-st;
1.220
```

The computation of $\text{ext}_D^1(N, D)$ only takes 1.220 s. Let us notice that all the computations are done generically. In other words, the results are valid for almost all values of the parameters (e.g., outside an algebraic hypersurface).

```
> Ext1[1];
```

¹The characteristic p of the ground field k can be chosen in the definition of the Ore algebra using the option “characteristic= p ”.

²*OreModules* and all examples of this appendix are available on the web page <http://wwwb.math.rwth-aachen.de/OreModules>.

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$Ext1[1]$ corresponds to the matrix L_0 returned by $EXT1(R)$ and defined in Algorithm 7.8. In our case, L_0 is the identity matrix which shows that $\text{ext}_D^1(N, D) = 0$ (see Remark 7.9). Therefore, the system is controllable, and thus, parametrizable (see Proposition 4.2 and Theorem 8.3). The parametrization of the system corresponds to the matrix $L_2 = Ext1[3]$ of $EXT1(R)$ (see Algorithm 7.8).

```
> map(collect, Ext1[3], Dt);
[-L2 Dt^4 + Dt^2 g]
[-Dt^4 L1 + Dt^2 g]
[L2 Dt^6 L1 M + (-L2 g m1 - L2 g M - g L1 M - L1 g m2) Dt^4
+ (g^2 M + g^2 m1 + m2 g^2) Dt^2]
[L2 Dt^4 L1 + (-L2 g - g L1) Dt^2 + g^2]
```

Thus, we obtain the parametrization $(x_1 : x_2 : x_3 : u)^T = L_2 z$ of $R(x_1 : x_2 : x_3 : u)^T = 0$. Using the fact that D is a principal ideal domain, then, by 1 of Theorem 3.6, we know that the D -module $M = D^{1 \times 4} / D^{1 \times 3} R$ is free, and thus, the system defined by R is flat.

```
> LeftInverse(Ext1[3], Alg);
[  L1^2          L2^2          0  -L1 + L2
  -----  -----
  g^2 (-L2 + L1)  g^2 (-L2 + L1)  g^2 (-L2 + L1) ]
```

$LeftInverse(Ext1[3], Alg)$ computes a left-inverse of the parametrization $L_2 = Ext1[3]$. We deduce that $z = (L_1^2 x_1 - L_2^2 x_2 + (L_1 - L_2) u) / (g^2 (L_1 - L_2))$ is a flat output of the system.

Let us notice that the difference of the pendula lengths $L_1 - L_2$ appears in the denominator of the flat output of the system. Thus, we need to study the non-generic case where $L_1 = L_2$.

```
> Rmod:=subs(L2=L1, evalm(R));
Rmod := [  m1 L1 Dt^2          m2 L1 Dt^2          -1  (M + m1 + m2) Dt^2
  m1 L1^2 Dt^2 - m1 L1 g          0          0          m1 L1 Dt^2
  0          m2 L1^2 Dt^2 - m2 L1 g          0          m2 L1 Dt^2 ]
> st:=time(): Ext1mod:=Exti(Involution(Rmod, Alg), Alg, 1): time()-st;
0.959
> Ext1mod;
```

$$\left[\begin{bmatrix} L1 Dt^2 - g & 0 & 0 \\ 0 & L1 Dt^2 - g & 0 \\ 0 & 0 & L1 Dt^2 - g \end{bmatrix}, \begin{bmatrix} 1 & -1 & 0 & 0 \\ 0 & m1 g + m2 g & -1 & Dt^2 M \\ 0 & M L1 Dt^2 - g M - m1 g - m2 g & 1 & 0 \end{bmatrix}, \right. \\ \left. \begin{bmatrix} -Dt^2 \\ -Dt^2 \\ L1 Dt^4 M - Dt^2 m1 g - g M Dt^2 - Dt^2 m2 g \\ L1 Dt^2 - g \end{bmatrix} \right]$$

The first matrix of $Ext1mod$ is not an identity matrix, and thus, we know that $\text{ext}_D^1(N_{\text{mod}}, D) \neq 0$, where $N_{\text{mod}} = D^{1 \times 3} / D^{1 \times 4} \theta(R_{\text{mod}})$ and R_{mod} corresponds to R , where $L_2 = L_1$. Thus, the system is not controllable (see Proposition 4.2 and Theorem 8.3). The second matrix of $Ext1mod$ gives a (non minimal) family of generators of the torsion elements of $M_{\text{mod}} = D^{1 \times 4} / D^{1 \times 3} R_{\text{mod}}$, i.e., of the non-controllable elements of the system. The initial rows in the first two matrices of $Ext1mod$ shows that $d = x_1 - x_2$ satisfies $(L_1 \partial^2 - g) d = 0$ (non-controllable element). The third matrix of $Ext1mod$ gives a parametrization of the torsion-free part $M_{\text{mod}}/t(M_{\text{mod}})$ of M_{mod} , i.e., of the controllable part of the system. Finally, let us notice that it has only taken 0.959 s to obtain all these informations.

A.2 Linear differential algebraic equations

Let us consider the following example of a time-varying linear OD system which corresponds to a linear system of differential algebraic equations (DAEs) studied in [16].

Therefore, we introduce the Weyl algebra $D = A_1$ (see Example 2.3).

```
> Alg:=DefineOreAlgebra(diff=[Dt,t], polynom={t}):
```

The time-varying linear system is defined by means of the following matrix.

```
> R:=evalm([[ -t*Dt+1, t^2*Dt, -1, 0], [-Dt, t*Dt+1, 0, -1]]);
```

$$R := \begin{bmatrix} -tDt + 1 & t^2Dt & -1 & 0 \\ -Dt & tDt + 1 & 0 & -1 \end{bmatrix}$$

Then, the system is defined by $R(x_1 : x_2 : u_1 : u_2)^T = 0$ and we define the left D -module $M = D^{1 \times 4} / D^{1 \times 2} R$.

```
> R_adj:=Involution(R, Alg);
```

$$R_adj := \begin{bmatrix} tDt + 2 & Dt \\ -t^2Dt - 2t & -tDt \\ -1 & 0 \\ 0 & -1 \end{bmatrix}$$

Using the procedure `EXT1(R_{adj})`, we compute $\widetilde{\text{ext}}_D^1(N, D)$, where $N = D^{1 \times 2} / D^{1 \times 4} R_{adj}$ is the left D -module associated with $R_{adj} = \theta(R) \in D^{4 \times 2}$.

```
> st:=time(): Ext1:=Exti(R_adj, Alg, 1): time()-st; Ext1[1];
```

```
0.301
```

$$\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

This shows that the left D -module $M = D^{1 \times 4} / D^{1 \times 2} R$ is a torsion-free D -module (see Remark 7.9), and thus, a projective D -module (see 1 of Theorem 3.6).

Then, a parametrization L_2 of the system is given by the following matrix of operators.

```
> Ext1[3];
```

$$\begin{bmatrix} t & 1 \\ 1 & 0 \\ 0 & -tDt + 1 \\ 0 & -Dt \end{bmatrix}$$

Thus, we obtain the parametrization $(x_1 : x_2 : x_3 : u)^T = L_2 z$ of $R(x_1 : x_2 : x_3 : u)^T = 0$. The system is flat, i.e., the left D -module $M = D^{1 \times 4} / D^{1 \times 2} R$ is free, iff the parametrization L_2 admits a left-inverse. Let us check whether or not L_2 admits a left-inverse.

```
> LeftInverse(Ext1[3], Alg);
```

$$P := \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & -t \end{bmatrix}$$

We see that the system is flat and a flat output is defined by $(z_1 : z_2)^T = P(x_1 : x_2 : x_3 : u)^T$.

A.3 Wind tunnel model

In this example, we consider again the linear differential time-delay system (4) defined in 3.2. We first need to define the Ore algebra $D_h = \mathbb{R}(a, k, \zeta, \omega)[t, s][\partial; \sigma_1, \delta_1][\delta_h; \sigma_2, \delta_2]$ of differential time-delay operators.

```
> Alg:=DefineOreAlgebra(diff=[Dt,t], dual_shift=[delta,s], polynom={t,s},
> comm={a, omega, zeta, k});
```

The linear differential time-delay system is defined by matrix (5).

```
> R:=evalm([[Dt+a, -k*a*delta, 0, 0], [0, Dt, -1, 0], [0, omega^2,
> Dt+2*zeta*omega, -omega^2]]);
```

$$R := \begin{bmatrix} Dt + a & -k a \delta & 0 & 0 \\ 0 & Dt & -1 & 0 \\ 0 & \omega^2 & Dt + 2 \zeta \omega & -\omega^2 \end{bmatrix}$$

```
> R_adj:=linalg[transpose](R);
```

$$R_{adj} := \begin{bmatrix} Dt + a & 0 & 0 \\ -k a \delta & Dt & \omega^2 \\ 0 & -1 & Dt + 2 \zeta \omega \\ 0 & 0 & -\omega^2 \end{bmatrix}$$

The Gröbner basis G defined in Example 5.5 can be computed as follows.

```
> Integrability(R_adj, Alg);
```

$$\begin{aligned} & [\omega^2 k a \delta \mu_1 + \omega^2 Dt \mu_2 + \omega^2 a \mu_2 + \omega^2 Dt^2 \mu_3 + \omega^2 a Dt \mu_3 + Dt^3 \mu_4 + 2 Dt^2 \zeta \omega \mu_4 \\ & + a Dt^2 \mu_4 + Dt \omega^2 \mu_4 + 2 a Dt \zeta \omega \mu_4 + a \omega^2 \mu_4, \lambda_3 \omega^2 + \mu_4, \\ & \omega^2 \lambda_2 + Dt \mu_4 + \omega^2 \mu_3 + 2 \zeta \omega \mu_4, \\ & \omega^2 \lambda_1 k a \delta + Dt^2 \mu_4 + \omega^2 Dt \mu_3 + 2 Dt \zeta \omega \mu_4 + \omega^2 \mu_2 + \omega^2 \mu_4, \lambda_1 Dt + \lambda_1 a - \mu_1] \end{aligned}$$

The syzygy module of $D_h^{1 \times 4} R^T$ can be computed using $\text{SYZYG}(R_{adj})$ (see Example 5.5).

```
> SyzygyModule(R_adj, Alg);
```

$$[\omega^2 k a \delta, Dt \omega^2 + a \omega^2, \omega^2 Dt^2 + \omega^2 a Dt, Dt \omega^2 + a \omega^2 + Dt^3 + 2 Dt^2 \zeta \omega + a Dt^2 + 2 a Dt \zeta \omega]$$

The Gröbner basis G defined in Example 7.4 can be computed as follows.

```
> Integrability(linalg[transpose](S), Alg);
```

$$[-\omega^2 \mu_4 + \omega^2 \mu_2 + Dt \mu_3 + 2 \zeta \omega \mu_3, -\mu_3 + Dt \mu_2, -k a \delta \mu_2 + Dt \mu_1 + a \mu_1, \lambda_1 \omega^2 k a \delta - \mu_1, \lambda_1 Dt \omega^2 + \lambda_1 a \omega^2 - \mu_2]$$

The syzygy module $D_h^{1 \times 4} R_{-1}$ can be computed using $\text{SYZYG}(R_{-1})$ (see Example 7.4).

```
> L:=SyzygyModule(linalg[transpose](S), Alg);
```

$$L := \begin{bmatrix} Dt + a & -k a \delta & 0 & 0 \\ 0 & \omega^2 & Dt + 2 \zeta \omega & -\omega^2 \\ 0 & Dt & -1 & 0 \end{bmatrix}$$

Finally, we compute $\text{QUOTIENT}(L, R)$ (see Example 7.7) as follows.

```
> Q:=Quotient(L, R, Alg);
```

$$Q := \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

We deduce that $\text{ext}_{D_h}^1(N, D_h) = 0$, where $N = D_h^{1 \times 3} / D_h^{1 \times 4} R^T$ (see Remark 7.9), and thus, system (4) is controllable and parametrizable (see Proposition 4.2 and Theorem 8.3).

We can directly compute $\text{ext}_{D_h}^1(N, D_h)$ using $\text{EXT1}(R_{\text{adj}})$ defined in Algorithm 7.8.

```
> st:=time(): Ext1:=Exti(Involution(R, Alg), Alg, 1); time()-st;
```

$$\text{Ext1} := \left[\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \begin{bmatrix} Dt + a & -k a \delta & 0 & 0 \\ 0 & \omega^2 & Dt + 2 \zeta \omega & -\omega^2 \\ 0 & Dt & -1 & 0 \end{bmatrix}, \right. \\ \left. \begin{bmatrix} -\omega^2 k a \delta \\ -Dt \omega^2 - a \omega^2 \\ -\omega^2 Dt^2 - \omega^2 a Dt \\ -Dt^3 - 2 Dt^2 \zeta \omega - a Dt^2 - Dt \omega^2 - 2 a Dt \zeta \omega - a \omega^2 \end{bmatrix} \right]$$

0.819

The first two matrices in *Ext1* are Q and L . Moreover, *Ext1*[3] gives (up to the sign) the parametrization (30) of system (4), i.e., we have $(x_1 : x_2 : x_2 : u)^T = \text{Ext1}[3] z$, where z is an arbitrary function of t .

We compute $\text{ext}_{D_h}^2(N, D_h)$ in order to check whether or not system (30) is flat.

```
> Ext2:=Exti(Involution(R, Alg), Alg, 2);
```

$$\text{Ext2} := \left[\begin{bmatrix} \delta \\ Dt + a \end{bmatrix}, [1], \text{SURJ}(1), \text{INJ}(1) \right]$$

Since the first matrix in *Ext2* is not an identity matrix, we know that $\text{ext}_{D_h}^2(N, D_h) \neq 0$ (see Remark 7.9). Hence, $M = D_h^{1 \times 4} / D_h^{1 \times 3} R$ is a torsion-free but not a free D_h -module, and thus, (4) is not a flat system. Finally, let us notice that (14) is equivalent to the reduced system:

$$(\partial + a)y = 0, \quad \delta_h y = 0.$$

Then, the formal obstructions of flatness are defined by π -POLYNOMIAL($R_{\text{adj}}, \{\partial, \delta_h\}$).

```
> PiPolynomial(R, Alg);
```

$$[\delta, Dt + a]$$

The π -polynomial, such that $(D_h)_\pi \otimes_{D_h} M$ is a free $(D_h)_\pi$ -module, is defined by the generator of the principal ideal π -POLYNOMIAL($R_{\text{adj}}, \{\delta_h\}$) of $\mathbb{R}(a, k, \zeta, \omega)[\delta_h; \sigma_2, \delta_2]$.

```
> PiPolynomial(R, Alg, [delta]);
```

$$[\delta]$$

Therefore, we find that system (4) is δ_h -flat (see Example 9.6).

```
> PiPolynomial(R, Alg, [Dt]);
```

$$[Dt + a]$$

The fact that (4) is not a flat system is coherent with the fact that the full row-rank matrix R , defined by (5), does not admit a right-inverse (R admits a right-inverse iff the D_h -module M is projective, and thus, free by 2 of Theorem 3.6).

```
> RightInverse(R, Alg);
```

□

The fact that (4) is not a flat system is also coherent with the fact that its parametrization (30) does not admit a left-inverse (a linear system is flat iff it is parametrizable and its parametrization admits a left-inverse).

```
> LeftInverse(Ext1[3], Alg);
```

□

But, we have shown that system (4) is δ_h -flat, and thus, the $D_h[\delta_h^{-1}]$ -module $D_h[\delta_h^{-1}] \otimes_{D_h} M$ is free. Let us compute a basis of the free $D_h[\delta_h^{-1}]$ -module $D_h[\delta_h^{-1}] \otimes_{D_h} M$. In order to do that, we compute a left-inverse S of the parametrization $Ext1[3]$ in the commutative polynomial ring $D_h[\delta_h^{-1}]$.

```
> S:=LocalLeftInverse(Ext1[3], [delta], Alg);
```

$$S := \begin{bmatrix} 1 & & & \\ -\frac{1}{\delta \omega^2 k a} & 0 & 0 & 0 \end{bmatrix}$$

By construction, we have $S Ext1[3] = 1$.

```
> simplify(evalm(S&*Ext1[3]));
```

[1]

Hence, we obtain that $z = S(x_1 : x_2 : x_3 : u)^T = -\delta_h^{-1} x_1 / (\omega^2 k a)$ is a basis of the $D_h[\delta_h^{-1}]$ -module $D_h[\delta_h^{-1}] \otimes_{D_h} M$ because we have $(x_1 : x_2 : x_3 : u)^T = Ext1[3] z$ and $z = -\delta_h^{-1} x_1 / (\omega^2 k a) \in M$.

Let us finally point out that we can also substitute $z = -\delta_h^{-1} x_1 / (\omega^2 k a)$ into the parametrization $(x_1 : x_2 : x_3 : u)^T = Ext1[3] z$ of system (4) in order to express the system variables in terms of x_1 .

```
> T:=simplify(evalm(Ext1[3]&*S));
```

$$T := \begin{bmatrix} 1 & 0 & 0 & 0 \\ \frac{Dt + a}{k a \delta} & 0 & 0 & 0 \\ \frac{Dt(Dt + a)}{k a \delta} & 0 & 0 & 0 \\ \frac{Dt \omega^2 + a \omega^2 + Dt^3 + 2 Dt^2 \zeta \omega + a Dt^2 + 2 a Dt \zeta \omega}{\omega^2 k a \delta} & 0 & 0 & 0 \end{bmatrix}$$

We obtain $(x_1 : x_2 : x_3 : u)^T = T x_1$, and thus, x_1 is also a basis of the module $D_h[\delta_h^{-1}] \otimes_{D_h} M$ over $D_h[\delta_h^{-1}]$, and thus, a flat output of system (4) over $D_h[\delta_h^{-1}]$. To finish, let us notice that, by imposing x_1 to be a desired trajectory $x_{1d}(t)$, we obtain the corresponding open-loop input [20]:

$$u_d(t) = \frac{1}{\omega^2 a k} \left(\left(\frac{d}{dt} + 2 \zeta \omega \frac{d}{dt} + \omega^2 \right) \left(\frac{d}{dt} + a \right) \right) x_{1d}(t + h).$$

A.4 A two reflector antenna

Let us consider the example of a two reflector antenna [20]. Any linear differential constant time-delay systems can be studied similarly. We refer to [20, 21] for more examples.

```
> Alg:=DefineOreAlgebra(diff=[Dt,t], dual_shift=[delta,s], polynom={t,s},
> comm={K1,K2,Te,Kp,Kc});
```

The system of the two reflector antenna is defined by the following matrix with entries in the commutative polynomial ring $D_h = \mathbb{R}(K1, K2, Te, Kp, Kc)[\partial; \sigma_1, \delta_1][\delta_h; \sigma_2, \delta_2]$ of differential time-delay operators.

```

> R:=evalm([[Dt, -K1, 0, 0, 0, 0, 0, 0, 0],
> [0, Dt+K2/Te, 0, 0, 0, 0, -Kp/Te*delta, -Kc/Te*delta, -Kc/Te*delta],
> [0, 0, Dt, -K1, 0, 0, 0, 0, 0],
> [0, 0, 0, Dt+K2/Te, 0, 0, -Kc/Te*delta, -Kp/Te*delta, -Kc/Te*delta],
> [0, 0, 0, 0, Dt, -K1, 0, 0, 0],
> [0, 0, 0, 0, 0, Dt+K2/Te, -Kc/Te*delta, -Kc/Te*delta, -Kp/Te*delta]]);
R := \begin{bmatrix} Dt & -K1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & Dt + \frac{K2}{Te} & 0 & 0 & 0 & 0 & -\frac{Kp \delta}{Te} & -\frac{Kc \delta}{Te} & -\frac{Kc \delta}{Te} \\ 0 & 0 & Dt & -K1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & Dt + \frac{K2}{Te} & 0 & 0 & -\frac{Kc \delta}{Te} & -\frac{Kp \delta}{Te} & -\frac{Kc \delta}{Te} \\ 0 & 0 & 0 & 0 & Dt & -K1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & Dt + \frac{K2}{Te} & -\frac{Kc \delta}{Te} & -\frac{Kc \delta}{Te} & -\frac{Kp \delta}{Te} \end{bmatrix}
> R_adj:=Involution(R, Alg):

```

Let us check whether or not the system, defined by the matrix R , is controllable and, if it is the case, let us find one of its parametrizations. In order to do that, we need to compute $\text{ext}_{D_h}^1(N, D_h)$, where $N = D_h^{1 \times 6} / D_h^{1 \times 9} R$. The displayed result corresponds to L_0 in the output of EXT1.

```

> st:=time(): Ext1:=Exti(R_adj, Alg, 1): time()-st; Ext1[1];
2.410
\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}

```

We obtain that $t(M) = \text{ext}_{D_h}^1(N, D_h) = 0$ (see Remark 7.9), where $M = D_h^{1 \times 9} / D_h^{1 \times 6} R$, and thus, the system of two reflector antenna is controllable (see Proposition 4.2 and Theorem 8.3).

Then, the matrix L_2 , defined by

```

> Ext1[3];
\begin{bmatrix} Kc \delta K1 & Kc \delta K1 & Kp K1 \delta \\ Kc Dt \delta & Kc Dt \delta & Kp Dt \delta \\ Kc \delta K1 & Kp K1 \delta & Kc \delta K1 \\ Kc Dt \delta & Kp Dt \delta & Kc Dt \delta \\ Kp K1 \delta & Kc \delta K1 & Kc \delta K1 \\ Kp Dt \delta & Kc Dt \delta & Kc Dt \delta \\ 0 & 0 & Dt^2 Te + K2 Dt \\ 0 & Dt^2 Te + K2 Dt & 0 \\ Dt^2 Te + K2 Dt & 0 & 0 \end{bmatrix}

```

is a parametrization of the two reflector antenna. The two reflector antenna is not a flat system because we have $\text{ext}_{D_h}^2(N, D_h) \neq 0$ as it is shown below.

```

> st:=time(): Ext2:=Exti(R_adj, Alg, 2): time()-st; Ext2[1];
1.931
\begin{bmatrix} \delta & 0 & 0 \\ Dt^2 Te + K2 Dt & 0 & 0 \\ 0 & \delta & 0 \\ 0 & Dt^2 Te + K2 Dt & 0 \\ 0 & 0 & \delta \\ 0 & 0 & Dt^2 Te + K2 Dt \end{bmatrix}

```

Since the torsion-free degree $i(M)$ of M is equal to 1 (see Proposition 9.4), we can find a polynomial π containing only one of the indeterminates Dt and δ such that $(D_h)_\pi \otimes_{D_h} M$ is a free $(D_h)_\pi$ -module. We study polynomials in δ_h .

```
> PiPolynomial(R, Alg, [delta]);
```

[δ]

So, we conclude that the two reflector antenna is δ_h -free [20]. Let us compute a basis of the $D_h[\delta_h^{-1}]$ -module $D_h[\delta_h^{-1}] \otimes_{D_h} M$. In order to do that, let us compute a left-inverse S of $Ext1[3]$ in $D_h[\delta_h^{-1}]$.

```
> S:=LocalLeftInverse(Ext1[3], [delta], Alg);
```

$$S := \begin{bmatrix} -\frac{Kc}{\delta K1 \%1} & 0 & -\frac{Kc}{\delta K1 \%1} & 0 & \frac{Kp + Kc}{\delta K1 \%1} & 0 & 0 & 0 & 0 \\ -\frac{Kc}{\delta K1 \%1} & 0 & \frac{Kp + Kc}{\delta K1 \%1} & 0 & -\frac{Kc}{\delta K1 \%1} & 0 & 0 & 0 & 0 \\ \frac{Kp + Kc}{\delta K1 \%1} & 0 & -\frac{Kc}{\delta K1 \%1} & 0 & -\frac{Kc}{\delta K1 \%1} & 0 & 0 & 0 & 0 \end{bmatrix}$$

$\%1 := Kp^2 - 2Kc^2 + KpKc$

We easily check that $S \in D_h[\delta_h^{-1}]^{3 \times 9}$ satisfies $S Ext1[3] = I_3$.

```
> simplify(evalm(S&*Ext1[3]));
```

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Hence, in the $D_h[\delta_h^{-1}]$ -module $D_h[\delta_h^{-1}] \otimes_{D_h} M$, we have

$$(z_1 : z_2 : z_3)^T = S (x_1 : \dots : x_6 : u_1 : u_2 : u_3)^T, \quad (42)$$

and thus, $\{z_1, z_2, z_3\}$ is a basis of the $D_h[\delta_h^{-1}]$ -module $D_h[\delta_h^{-1}] \otimes_{D_h} M$ which satisfies:

$$(x_1 : \dots : x_6 : u_1 : u_2 : u_3)^T = Ext1[3] (z_1 : z_2 : z_3)^T.$$

Finally, if we substitute (42) into the parametrization $Ext1[3]$ of the system, we obtain

$$(x_1 : \dots : x_6 : u_1 : u_2 : u_3)^T = T (x_1 : \dots : x_6 : u_1 : u_2 : u_3)^T,$$

where the matrix $T \in D_h[\delta_h^{-1}]^{9 \times 9}$ is defined by:

```
> T:=simplify(evalm(Ext1[3]&*S));
```

$$T := \begin{bmatrix} 1, 0, 0, 0, 0, 0, 0, 0, 0 \\ \frac{Dt}{K1}, 0, 0, 0, 0, 0, 0, 0, 0 \\ 0, 0, 1, 0, 0, 0, 0, 0, 0 \\ 0, 0, \frac{Dt}{K1}, 0, 0, 0, 0, 0, 0 \\ 0, 0, 0, 0, 1, 0, 0, 0, 0 \\ 0, 0, 0, 0, \frac{Dt}{K1}, 0, 0, 0, 0 \\ \frac{Dt (Te Dt + K2) (Kp + Kc)}{\delta K1 \%1}, 0, \%2, 0, \%2, 0, 0, 0, 0 \\ \%2, 0, \frac{Dt (Te Dt + K2) (Kp + Kc)}{\delta K1 \%1}, 0, \%2, 0, 0, 0, 0 \\ \%2, 0, \%2, 0, \frac{Dt (Te Dt + K2) (Kp + Kc)}{\delta K1 \%1}, 0, 0, 0, 0 \end{bmatrix}$$

$$\%1 := Kp^2 - 2 Kc^2 + Kp Kc$$

$$\%2 := -\frac{Dt (Te Dt + K2) Kc}{\delta K1 \%1}$$

Then, we notice $(x_2 : x_4 : x_6 : u_1 : u_2 : u_3)$ are only expressed in terms of x_1, x_3 and x_5 . Therefore, $\{x_1, x_3, x_5\}$ is also a basis of the $D_h[\delta_h^{-1}]$ -module $D_h[\delta_h^{-1}] \otimes_{D_h} M$ of rank 3 (compare with [20]).

A.5 An electric transmission line

To finish with linear differential time-delay systems, we shall study the example of an electric transmission line [34]. We shall exhibit an explicit parametrization of this system. It seems that no parametrization for such a system was previously known [20]. This can be easily explained by the fact that it was very difficult to guess such a parametrization (indeed, the characterization in terms of the extension functor of the existence of a parametrization has only been recently developed in [27]). Moreover, it becomes very difficult to avoid the use of a symbolic computation program in order to handle all the computations.

We first introduce $D_h = \mathbb{R}(a_0, a_1, a_2, a_3, a_4, a_5, b_0)[t, s][\partial; \sigma_1, \delta_1][\delta_h; \sigma_2, \delta_2]$, the Ore algebra of differential time-delay operators.

```
> Alg:=DefineOreAlgebra(diff=[Dt,t], dual_shift=[delta,s], polynom={t,s},
> comm={a[0],a[1],a[2],a[3],a[4],a[5],b[0]}):
```

The electric transmission line is defined by means of the following matrix:

```
> R:=evalm([[Dt+a[0], -(a[4]*Dt+a[0])*delta, -a[0], 0, -b[0]*Dt],
> [-delta*(a[5]*Dt+a[1]), Dt+a[1], 0, a[1], 0],
> [a[2], -a[2]*a[4]*delta, Dt, 0, -a[2]*b[0]],
> [a[3]*a[5]*delta, -a[3], 0, Dt, 0]]);
```

$$R := \begin{bmatrix} Dt + a_0 & -(a_4 Dt + a_0) \delta & -a_0 & 0 & -b_0 Dt \\ -\delta (a_5 Dt + a_1) & Dt + a_1 & 0 & a_1 & 0 \\ a_2 & -a_2 a_4 \delta & Dt & 0 & -a_2 b_0 \\ a_3 a_5 \delta & -a_3 & 0 & Dt & 0 \end{bmatrix}$$

```
> R_adj:=Involution(R, Alg):
> st:=time(): Ext1:=Exti(R_adj, Alg, 1): time()-st; Ext1[1];
```

10.351

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Therefore, by Proposition 4.2 and Theorem 8.3, we find that the electric transmission line is controllable and parametrizable and a parametrization is given by the following matrix.

> Ext1[3];

$$\begin{aligned}
& [-b_0 Dt^4 - Dt^2 b_0 a_1 a_3 - a_0 a_2 b_0 Dt^2 - a_1 a_0 a_2 b_0 a_3 - a_0 a_1 a_2 b_0 Dt - a_1 b_0 Dt^3] \\
& [-a_5 b_0 \delta Dt^4 - a_5 \delta Dt^2 b_0 a_1 a_3 - a_1 b_0 \delta Dt^3 - a_0 a_2 a_5 b_0 \delta Dt^2 \\
& - a_0 a_1 a_2 a_5 a_3 \delta b_0 - a_0 a_1 a_2 b_0 \delta Dt] \\
& [a_0 a_2 a_1 b_0 a_3 a_5 \delta^2 - a_0 a_2 b_0 Dt^2 - a_1 a_0 a_2 b_0 a_3 + a_0 a_1 a_2 b_0 \delta^2 Dt \\
& - a_0 a_1 a_2 b_0 Dt + a_0 a_2 a_5 \delta^2 b_0 Dt^2] \\
& [a_0 a_1 a_2 a_5 a_3 \delta b_0 - \delta Dt^2 b_0 a_1 a_3 + a_5 \delta Dt^2 b_0 a_1 a_3 - a_0 a_1 a_2 a_3 \delta b_0] \\
& [-Dt^4 - a_1 Dt^3 - a_0 a_1 Dt^2 - a_0 Dt^3 + a_5 Dt^4 \delta^2 a_4 + a_1 a_5 Dt^2 a_3 a_4 \delta^2 + a_1 Dt^3 a_4 \delta^2 \\
& + a_0 a_2 a_5 Dt^2 a_4 \delta^2 + a_0 Dt^3 \delta^2 a_5 - a_1 a_3 a_0 a_2 - a_0 a_1 a_2 Dt - a_0 a_1 a_3 Dt \\
& + a_0 a_1 Dt^2 \delta^2 + a_0 a_1 a_2 a_5 a_3 a_4 \delta^2 + a_0 a_1 a_2 Dt a_4 \delta^2 + a_0 a_1 a_3 \delta^2 Dt a_5 \\
& - a_1 Dt^2 a_3 - a_0 a_2 Dt^2]
\end{aligned}$$

> st:=time(): Ext2:=Exti(R_adj, Alg, 2): time()-st; Ext2[1];

6.990

$$\begin{aligned}
& [-\delta a_1^2 a_5 a_3^2 + 2 a_0 a_1 a_2 a_5 a_3 \delta - Dt \delta a_2 a_1 a_0 + \delta Dt a_1^2 a_3 + \delta a_5 a_2 a_0 Dt a_1 \\
& - \delta a_1^2 a_5 a_3 Dt + \delta^3 a_1^2 a_2 a_0 - 2 a_5^2 a_2 a_0 a_1 a_3 \delta^3 + a_5^2 a_2^2 a_0^2 \delta^3 + a_1^2 a_5^2 a_3^2 \delta^3 \\
& - a_5 a_2^2 a_0^2 \delta - a_1^2 \delta a_2 a_0] \\
& [Dt \delta^2 a_1 - Dt^2 + a_1 a_3 a_5 \delta^2 - Dt a_1 - a_1 a_3 - a_5 \delta^2 a_2 a_0] \\
& [\delta a_2 a_0 + \delta Dt^2] \\
& [a_1 Dt^3 + Dt^2 a_1^2 + a_0 a_2 a_5 Dt^2 - a_5 Dt^2 a_1 a_3 + \delta^2 a_1^2 a_2 a_0 - 2 a_5^2 a_2 a_0 a_1 a_3 \delta^2 \\
& + a_5^2 a_2^2 a_0^2 \delta^2 + a_1^2 a_5^2 a_3^2 \delta^2 + Dt a_1^2 a_3 + a_5 a_2 a_0 Dt a_1 - a_1^2 a_5 a_3 Dt \\
& + a_1 a_5 a_3 a_2 a_0 - a_1^2 a_5 a_3^2]
\end{aligned}$$

Since we have $\text{ext}_{D_h}^2(N, D_h) \neq 0$, where $N = D_h^{1 \times 4} / D_h^{1 \times 5} R^T$, the transmission line is not a flat system. Thus, we have $i(M) = 1$, and we can find a polynomial π that contains only Dt or δ such that $(D_h)_\pi \otimes_{D_h} M$ is a free $(D_h)_\pi$ -module. The third argument for π -POLYNOMIAL selects the variable for the π -polynomial:

> pi:=PiPolynomial(R, Alg, [delta]): factor(pi);

$$\begin{aligned}
& [\delta(a_5^2 a_2^2 a_0^2 \delta^4 - 2 \delta^2 a_5 a_2^2 a_0^2 + a_2^2 a_0^2 - 2 a_5^2 a_2 a_0 a_1 a_3 \delta^4 + 4 \delta^2 a_1 a_5 a_3 a_2 a_0 \\
& + a_1^2 a_2 a_0 - 2 \delta^2 a_1^2 a_2 a_0 - 2 a_1 a_3 a_0 a_2 + \delta^4 a_1^2 a_2 a_0 + a_1^2 a_5^2 a_3^2 \delta^4 \\
& - 2 \delta^2 a_1^2 a_5 a_3^2 + a_1^2 a_3^2)]
\end{aligned}$$

We conclude that the system is π -free, where π is the previous polynomial in δ_h , and thus, the $D_h[\pi^{-1}]$ -module $D_h[\pi^{-1}] \otimes_{D_h} M$ is free. Let us compute a basis of the $D_h[\pi^{-1}]$ -module $D_h[\pi^{-1}] \otimes_{D_h} M$.

> S:=LocalLeftInverse(Ext1[3], pi, Alg):

> T:=map(collect, S, delta);

$$\begin{aligned}
T := & \left[-\frac{\delta(\delta^4 a_0 a_5^2 + (-a_5 a_0 - a_0 a_5^2 + a_1 - a_1 a_5) \delta^2 - a_1 + a_1 a_5 + a_5 a_0)}{\%2 a_0 b_0 (-1 + a_5)}, \right. \\
& \frac{(a_5 a_0 - a_1 a_5 a_4 + a_1 a_4) \delta^4 + (-a_5 a_0 + a_1 a_5 a_4 - a_1 a_4 - a_0) \delta^2 + a_0}{\%2 a_0 b_0 (-1 + a_5)}, \\
& \left. -\frac{\delta((-a_1 a_5 a_3 + a_5 a_2 a_0) \delta^2 - a_0 a_2 + a_1 a_3)}{\%2 a_0 a_2 b_0}, \right. \\
& \left. \frac{(a_0 a_5^2 a_2 - a_5^2 a_1 a_3 + a_1^2) \delta^4 + (2 a_1 a_5 a_3 - 2 a_5 a_2 a_0 - 2 a_1^2) \delta^2 + a_1^2 + a_0 a_2 - a_1 a_3}{\%2 a_1 a_3 b_0 (-1 + a_5)}, \right. \\
& \left. -\frac{\delta a_1 (\delta^2 - 1)}{\%2 a_0} \right] \\
\%1 := & a_1^2 a_2 a_0 \\
\%2 := & (a_0^2 a_2^2 a_5^2 + \%1 - 2 a_5^2 a_1 a_3 a_2 a_0 + a_5^2 a_1^2 a_3^2) \delta^5 \\
& + (-2 a_5 a_1^2 a_3^2 + 4 a_0 a_1 a_2 a_5 a_3 - 2 a_1^2 a_2 a_0 - 2 a_0^2 a_5 a_2^2) \delta^3 \\
& + (\%1 - 2 a_1 a_3 a_2 a_0 + a_2^2 a_0^2 + a_1^2 a_3^2) \delta
\end{aligned}$$

We check that the matrix $T \in (D_h)^{1 \times 5}$ is a left-inverse of $Ext1[3]$, i.e., we have $T Ext1[3] = 1$.

```
> simplify(evalm(T*Ext1[3]));
```

[1]

Hence, $z = T(x_1 : \dots : x_4 : u)^T$ is a basis of the $D_h[\pi^{-1}]$ -module $D_h[\pi^{-1}] \otimes_{D_h} M$ which satisfies $(x_1 : \dots : x_4 : u)^T = Ext1[3]z$.

A.6 Einstein equations

Let us show that the results exposed in this paper can also be interesting for the study of underdetermined systems of PDEs coming from mathematical physics. We shall study the parametrizability of the Einstein equations using the linearized Ricci equations in the vacuum [24] (see also [37]).

Let us introduce the Weyl algebra $D = A_4(x_1, x_2, \text{ and } x_3 \text{ stand for the three space components and } x_4 = ct \text{ for the time } t \text{ component up to the speed of light factor})$.

```
> Alg:=DefineOreAlgebra(diff=[D1,x1], diff=[D2,x2], diff=[D3,x3],
> diff=[D4,x4], polynom={x1,x2,x3,x4});
```

The linearized Ricci equations in the vacuum are defined by the following 10×10 matrix of partial differential operators.

```
> R:=evalm(
> [[D2^2+D3^2-D4^2, D1^2, D1^2, -D1^2, -2*D1*D2, 0, 0, -2*D1*D3, 0,
> 2*D1*D4],
> [D2^2, D1^2+D3^2-D4^2, D2^2, -D2^2, -2*D1*D2, -2*D2*D3, 0, 0,
> 2*D2*D4, 0],
> [D3^2, D3^2, D1^2+D2^2-D4^2, -D3^2, 0, -2*D2*D3, 2*D3*D4, -2*D1*D3,
> 0, 0],
> [D4^2, D4^2, D4^2, D1^2+D2^2+D3^2, 0, 0, -2*D3*D4, 0, -2*D2*D4,
> -2*D1*D4],
> [0, 0, D1*D2, -D1*D2, D3^2-D4^2, -D1*D3, 0, -D2*D3, D1*D4, D2*D4],
> [D2*D3, 0, 0, -D2*D3, -D1*D3, D1^2-D4^2, D2*D4, -D1*D2, D3*D4, 0],
> [D3*D4, D3*D4, 0, 0, 0, -D2*D4, D1^2+D2^2, -D1*D4, -D2*D3, -D1*D3],
> [0, D1*D3, 0, -D1*D3, -D2*D3, -D1*D2, D1*D4, D2^2-D4^2, 0, D3*D4],
> [D2*D4, 0, D2*D4, 0, -D1*D4, -D3*D4, -D2*D3, 0, D1^2+D3^2, -D1*D2],
> [0, D1*D4, D1*D4, 0, -D2*D4, 0, -D1*D3, -D3*D4, -D1*D2,
> D2^2+D3^2]]);
```

$$R := \begin{bmatrix} D2^2 + D3^2 - D4^2, D1^2, D1^2, -D1^2, -2D1D2, 0, 0, -2D1D3, 0, 2D1D4 \\ D2^2, D1^2 + D3^2 - D4^2, D2^2, -D2^2, -2D1D2, -2D2D3, 0, 0, 2D2D4, 0 \\ D3^2, D3^2, D1^2 + D2^2 - D4^2, -D3^2, 0, -2D2D3, 2D3D4, -2D1D3, 0, 0 \\ D4^2, D4^2, D4^2, D1^2 + D2^2 + D3^2, 0, 0, -2D3D4, 0, -2D2D4, -2D1D4 \\ 0, 0, D1D2, -D1D2, D3^2 - D4^2, -D1D3, 0, -D2D3, D1D4, D2D4 \\ D2D3, 0, 0, -D2D3, -D1D3, D1^2 - D4^2, D2D4, -D1D2, D3D4, 0 \\ D3D4, D3D4, 0, 0, 0, -D2D4, D1^2 + D2^2, -D1D4, -D2D3, -D1D3 \\ 0, D1D3, 0, -D1D3, -D2D3, -D1D2, D1D4, D2^2 - D4^2, 0, D3D4 \\ D2D4, 0, D2D4, 0, -D1D4, -D3D4, -D2D3, 0, D1^2 + D3^2, -D1D2 \\ 0, D1D4, D1D4, 0, -D2D4, 0, -D1D3, -D3D4, -D1D2, D2^2 + D3^2 \end{bmatrix}$$

> R_adj:=Involution(R, Alg);

$$R_adj := \begin{bmatrix} D2^2 + D3^2 - D4^2, D2^2, D3^2, D4^2, 0, D2D3, D3D4, 0, D2D4, 0 \\ D1^2, D1^2 + D3^2 - D4^2, D3^2, D4^2, 0, 0, D3D4, D1D3, 0, D1D4 \\ D1^2, D2^2, D1^2 + D2^2 - D4^2, D4^2, D1D2, 0, 0, 0, D2D4, D1D4 \\ -D1^2, -D2^2, -D3^2, D1^2 + D2^2 + D3^2, -D1D2, -D2D3, 0, -D1D3, 0, 0 \\ -2D1D2, -2D1D2, 0, 0, D3^2 - D4^2, -D1D3, 0, -D2D3, -D1D4, -D2D4 \\ 0, -2D2D3, -2D2D3, 0, -D1D3, D1^2 - D4^2, -D2D4, -D1D2, -D3D4, 0 \\ 0, 0, 2D3D4, -2D3D4, 0, D2D4, D1^2 + D2^2, D1D4, -D2D3, -D1D3 \\ -2D1D3, 0, -2D1D3, 0, -D2D3, -D1D2, -D1D4, D2^2 - D4^2, 0, -D3D4 \\ 0, 2D2D4, 0, -2D2D4, D1D4, D3D4, -D2D3, 0, D1^2 + D3^2, -D1D2 \\ 2D1D4, 0, 0, -2D1D4, D2D4, 0, -D1D3, D3D4, -D1D2, D2^2 + D3^2 \end{bmatrix}$$

Let us study whether or not the linearized Ricci equations are parametrizable. Let us notice that this problem is related to a question asked by J. Wheeler on the existence of potentials for the Einstein equations [24].

> st:=time(): Ext1:=Exti(R_adj, Alg, 1): time()-st; Ext1[1];
86.810

%1 := D3² + D2² - D4² + D1²

Therefore, we see that the linearized Ricci equations are not parametrizable because the system, defined by $R \in D^{10 \times 10}$, admits a family of 20 torsion elements which generate the torsion submodule of the D -module $M = D^{1 \times 10} / D^{1 \times 10} R$. Let us notice that every torsion element of the system satisfies the Dalemberertian equation, namely $(\Delta - c^2 \frac{\partial^2}{\partial t^2}) y = 0$ (travelling wave in space-time).

The list of 20 torsion elements of the system is given by the following 20×10 matrix.

> Ext1[2];

$$\begin{bmatrix} D2D4, 0, 0, 0, -D1D4, 0, 0, 0, D1^2, -D1D2 \\ D3D4, 0, 0, 0, 0, 0, D1^2, -D1D4, 0, -D1D3 \\ D2D3, 0, 0, 0, -D1D3, D1^2, 0, -D1D2, 0, 0 \\ D4^2, 0, 0, D1^2, 0, 0, 0, 0, 0, -2D1D4 \\ D3^2, 0, D1^2, 0, 0, 0, 0, -2D1D3, 0, 0 \\ D2^2, D1^2, 0, 0, -2D1D2, 0, 0, 0, 0, 0 \\ 0, D3D4, 0, 0, 0, -D2D4, D2^2, 0, -D2D3, 0 \\ 0, D4^2, 0, D2^2, 0, 0, 0, 0, -2D2D4, 0 \\ 0, D3^2, D2^2, 0, 0, -2D2D3, 0, 0, 0, 0 \\ 0, -D1D4, 0, 0, D2D4, 0, 0, 0, D1D2, -D2^2 \\ 0, -D1D3, 0, 0, D2D3, D1D2, 0, -D2^2, 0, 0 \\ 0, 0, D4^2, D3^2, 0, 0, -2D3D4, 0, 0, 0 \\ 0, 0, -D2D4, 0, 0, D3D4, D2D3, 0, -D3^2, 0 \\ 0, 0, -D1D4, 0, 0, 0, D1D3, D3D4, 0, -D3^2 \\ 0, 0, D1D2, 0, D3^2, -D1D3, 0, -D2D3, 0, 0 \\ 0, 0, 0, D2D3, 0, D4^2, -D2D4, 0, -D3D4, 0 \\ 0, 0, 0, D1D3, 0, 0, -D1D4, D4^2, 0, -D3D4 \\ 0, 0, 0, D1D2, D4^2, 0, 0, 0, -D1D4, -D2D4 \\ 0, 0, 0, 0, D3D4, -D1D4, D1D2, 0, 0, -D2D3 \\ 0, 0, 0, 0, 0, -D1D4, 0, D2D4, D1D3, -D2D3 \end{bmatrix}$$

The parametrization of the D -module $M/t(M) = D^{1 \times 10}/D^{1 \times 20} \text{Ext1}[2]$ is defined by:

> Ext1[3];

$$\begin{bmatrix} -2D1 & 0 & 0 & 0 \\ 0 & -2D2 & 0 & 0 \\ 0 & 0 & -2D3 & 0 \\ 0 & 0 & 0 & -2D4 \\ -D2 & -D1 & 0 & 0 \\ 0 & -D3 & -D2 & 0 \\ 0 & 0 & -D4 & -D3 \\ -D3 & 0 & -D1 & 0 \\ 0 & -D4 & 0 & -D2 \\ -D4 & 0 & 0 & -D1 \end{bmatrix}$$

Therefore, the underdetermined linear system of PDEs $\text{Ext1}[2]y = 0$, which is associated with the D -module $M/t(M) = D^{1 \times 10}/D^{1 \times 20} \text{Ext1}[2]$, is parametrized by $\text{Ext1}[3]$, i.e., we have $y = \text{Ext1}[3]z$, where $z = (z_1 : z_2 : z_3 : z_4)^T$ are four potentials.

A.7 Lie-Poisson structures

Finally, let us notice that the results developed in this paper can be applied to underdetermined linear systems of PDEs with variable coefficients that appear in some problems of mathematical physics. For instance, let us give an example coming from the study of *Lie-Poisson structures* [3, 35].

```
> Alg:=DefineOreAlgebra(diff=[D1,x1], diff=[D2,x2], diff=[D3,x3],
> polynom={x1,x2,x3}):
```

The following example appears in the study of the E_2 algebra [3]. The authors of [3] investigated the possibility to parametrize all the solutions of the system of PDEs defined by the following matrix.

```
> R:=evalm([[x1*D3, x2*D3, 0],
> [-x1*D2+x2*D1, -1, x2*D3],
> [-1, -x2*D1+x1*D2, x1*D3]]);
```

$$R := \begin{bmatrix} x1 D3 & x2 D3 & 0 \\ -x1 D2 + x2 D1 & -1 & x2 D3 \\ -1 & -x2 D1 + x1 D2 & x1 D3 \end{bmatrix}$$

Let $D = A_3$ be the Weyl algebra (see Example 2.3) and $M = D^{1 \times 3} / D^{1 \times 3} R$ be the left D -module associated with R . The previous problem can be solved by computing $\text{ext}_D^1(N, D)$, where $\tilde{N} = D^{1 \times 3} / D^{1 \times 3} \theta(R)$ is a left D -module and θ is the involution defined in 2 of Example 6.3.

```
> Ext1:=Exti(Involution(R, Alg), Alg, 1);
```

$$\text{Ext1} := \begin{bmatrix} D3 & 0 & 0 \\ -x2 D1 + x1 D2 & 0 & 0 \\ 0 & x2 D3 & 0 \\ 0 & x1 D3 & 0 \\ 0 & -x2 D1 + x1 D2 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \begin{bmatrix} x1 & x2 & 0 \\ D1 & D2 & D3 \\ -1 & -x2 D1 + x1 D2 & x1 D3 \end{bmatrix},$$

$$\begin{bmatrix} -x2 D3 \\ x1 D3 \\ -x1 D2 + x2 D1 \end{bmatrix}$$

We find that the system $R(F : G : H)^T = 0$ is not parametrizable because there exist two torsion elements in the left D -module M

$$\begin{cases} \Phi_1 = x_1 F + x_2 G, \\ \Phi_2 = \partial_1 F + \partial_2 G + \partial_3 H, \end{cases}$$

which satisfy:

$$\begin{cases} \partial_3 \Phi_1 = 0, \\ (-x_2 \partial_1 + x_1 \partial_2) \Phi_1 = 0, \end{cases} \quad \begin{cases} x_1 \partial_3 \Phi_2 = 0, \\ x_2 \partial_3 \Phi_2 = 0, \\ (-x_2 \partial_1 + x_1 \partial_2) \Phi_2 = 0. \end{cases}$$

However, the system of PDEs $\text{Ext1}[2] y = 0$ is parametrized by $y = \text{Ext1}[3] z$. Up to the mistake underlined in [35] concerning the existence of the torsion elements, we recover the parametrization exhibited in [3]. We refer the interested reader to [35] for more details.

The previous computation shows M is not a torsion left D -module even if R is a square matrix. Hence, R does not have full row rank. This result can be checked by computing a free resolution of the left D -module $M = D^{1 \times 3} / D^{1 \times 3} R$.

```
> Free:=FreeResolution(R,Alg);
```

$$\text{Free} := \text{table}([1 = \begin{bmatrix} x1 D3 & x2 D3 & 0 \\ -x1 D2 + x2 D1 & -1 & x2 D3 \\ -1 & -x2 D1 + x1 D2 & x1 D3 \end{bmatrix},$$

$$2 = [-x2 D1 + x1 D2 \quad x1 D3 \quad -x2 D3],$$

$$3 = \text{INJ}(1)$$

$$])$$

In particular, the left D -module $L = D^{1 \times 3}/D \text{Free}[2]$ is torsion-free as we have $L \cong D^{1 \times 3} R \subset D^{1 \times 3}$.

```
> ext:=Exti(Involution(Free[2], Alg), Alg, 1);
ext := [ [ 1 ], [ -x2 D1 + x1 D2  x1 D3  -x2 D3 ], [ [ D3      x1 D3      0
-D2    -x1 D2 + x2 D1  x2
-D1      -1          x1 ] ] ]
```

Therefore, the matrices $R \in D^{3 \times 3}$ and $ext[3]$ are two parametrizations of the left D -module $L = D^{1 \times 3}/D \text{Free}[2]$. Let us compute $\text{rank}_D L$.

```
> OreRank(Free[2], Alg);
```

2

Hence, we conclude that $y = Rz$ and $y = ext[3]z$ are not minimal parametrizations of the system $R(F : G : H)^T = 0$ because they depend on three arbitrary functions of (x_1, x_2, x_3) . Let us compute some minimal parametrizations of the system $R(F : G : H)^T = 0$.

```
> P:=MinimalParametrizations(Free[2], Alg);
```

$$P := \left[\left[\begin{array}{cc} D3 & x1 D3 \\ -D2 & -x1 D2 + x2 D1 \\ -D1 & -1 \end{array} \right], \left[\begin{array}{cc} D3 & 0 \\ -D2 & x2 \\ -D1 & x1 \end{array} \right], \left[\begin{array}{cc} x1 D3 & 0 \\ -x1 D2 + x2 D1 & x2 \\ -1 & x1 \end{array} \right] \right]$$

Then, we can check that $y = P[1]z$, $y = P[2]z$ and $y = P[3]z$ are three minimal parametrizations of the system $R(F : G : H)^T = 0$, where $z = (z_1 : z_2)^T$, and z_1 and z_2 are two arbitrary functions of x_1, x_2 and x_3 .

```
> seq(SyzygyModule(P[i], Alg), i=1..3);
```

```
%1, %1, %1
%1 := [ -x2 D1 + x1 D2  x1 D3  -x2 D3 ]
```

To finish, let us consider the Ore algebra $B_3 = \mathbb{R}(x_1, x_2, x_3)[\partial_1; \sigma_1, \delta_1][\partial_2; \sigma_2, \delta_2][\partial_3; \sigma_3, \delta_3]$, where σ_i and δ_i are defined as in the last part of Example 2.3 and let us define the left B_3 -module $M' = B_3^{1 \times 3}/B_3^{1 \times 3} R$ associated with R over B_3 . Since the domain of coefficients of B_3 is the *quotient field* of $\mathbb{R}[x_1, x_2, x_3]$, we are going to use the Weyl algebra $D = A_3$ (see Example 2.3) and allow our algorithms to divide by non-zero polynomials in x_1, x_2, x_3 . This is taken into account by `ExtiRat` below.

```
> st:=time(): ExtiRat(Involution(R, Alg), Alg, 1);
> time()-st;
```

$$\left[\left[\begin{array}{cc} D3 & 0 \\ -x1 D2 + x2 D1 & 0 \\ 0 & D3 \\ 0 & -x1 D2 + x2 D1 \end{array} \right], \left[\begin{array}{ccc} x1 & x2 & 0 \\ 0 & -x1^2 D2 + x1 x2 D1 - x2 & -x1^2 D3 \end{array} \right], \left[\begin{array}{c} x2 D3 \\ -x1 D3 \\ -x2 D1 + x1 D2 \end{array} \right] \right]$$

0.670

We find that the system $R(F : G : H)^T = 0$ is not parametrizable because there exist two torsion elements

$$\begin{cases} \Phi_1 = x_1 F + x_2 G, \\ \Phi_2 = (-x_1^2 \partial_2 + x_1 x_2 \partial_1 - x_2) G - x_1^3 \partial_3 H, \end{cases}$$

which both satisfy the system:

$$\begin{cases} \partial_3 \Phi_i = 0, \\ (-x_1 \partial_2 + x_2 \partial_1) \Phi_i = 0, \end{cases} \quad i = 1, 2.$$

We recover the torsion element Φ_1 exhibited in [35] as well as the parametrization of the torsion-free left B_3 -module $M'/t(M')$ given in [3].
