Une version discrète des asymptotiques de She : équations multigroupes de transport de neutrons

Résumé : Ce rapport est consacré à l'obtention des équations de diffusion multigroupe à partir des équations de Boltzmann. Le système limite couple les niveaux d'énergie dès le niveau zéro et les courants de diffusion.

Mots-clés : Equation de Boltzmann, approximation par diffusion, transport de neutron, harmoniques sphériques, équations de convection-diffusion

1 Introduction

Production of nuclear energy relies on the disintegration of atoms (Uranium or Plutonium), when subjected to collisions with neutrons. Therefore, reactor design requires an accurate description of the motion of the population of neutrons. The motion of neutrons is described through the evolution of the density $f(t, x, v)$ of neutrons occupying at time $t \geq 0$ the position $x \in \mathbb{R}^N$ and having velocity $v \in \mathbb{R}^N$. It will be convenient in what follows to see this last variable as $v = \sqrt{2e/m} \omega$, $m > 0$ being the mass of the neutron, $e \geq 0$ its energy and $\omega \in S^{N-1}$ the direction of the flight. The unknown f verifies a transport equation

$$\partial_t f + v \cdot \nabla_x f = Q(f) \quad (1)$$

that relates the free transport (left hand side) to the various interaction processes undergone by the neutrons and described through the operator $Q(f)$. The latter are essentially collisions. Furthermore, the number of neutrons in any volume, at any time, remains smaller than the number of atomic nuclei (10^{11} is a typical ratio) so that it is reasonable to assume that the most probable event is an elastic collision with the surrounding medium. Consequently, the right hand side of (1) is usually given by a Boltzmann linear operator

$$Q(f) = \int \sigma(x, v, v') f(t, x, v') dv' - \Sigma(x, v) f(t, x, v). \quad (2)$$

The transfer function $\sigma(x, v, v') \geq 0$ is such that $\sigma(x, v, v') dv$ represents the probability that a neutron impinging with velocity v' will have velocity in the volume dv around v after the collision; while $\Sigma(x, v) \geq 0$ is the so-called removal cross section. If the operator is conservative i.e. $\int Q(f) dv = 0$, which means that $\Sigma(x, v) = \int \sigma(x, v', v) dv'$, then absorption/fission events are neglected or compensated with scattering. One also says that the reactor is critical in this case. It is worth remarking that, since the ratio of the mass of the nuclei to the mass of the neutrons is very large, then, during an elastic collision, the energy of the neutron is practically unchanged; the main effect of such a collision is only to modify the direction of the flight. Notice also that inelastic scattering, with loss of energy, remains possible, but it can only occur for highly energetic neutrons.

On the other hand, nuclear engineers are motivated in the derivation of simplified models that describe the physics accurately enough but remain of moderate computational cost. In these applications, one encounters a very large range of energies, from $1/40$ eV to some Mev; and a first simplification arises by breaking the energy range into several disjoint energy groups: $[e_{min}, e_{Max}] = \bigcup_{i=1}^I [e_i, e_{i+1}]$. In most of the situations, the total number of groups I is finite. One assumes that the cross sections do not vary too much on the energy groups and neutrons evolve according to averaged quantities, such as average scattering cross sections. Consequently, one is led to semi-discrete versions of equation (1-2). This will be detailed in Section 2 below.

Next, a commonly used strategy consists in neglecting the angular variable ω and writing a diffusion equation for a macroscopic energy distribution function $\rho(t, x, e)$, e being the energy variable (discrete or continuous). Actually, one deals in this context with systems of

equations, coupled by the energy variable, which have usually the following form

$$\begin{aligned} \partial_t \rho(t, x, e) - \operatorname{div}_x (D(x, e) \nabla_x \rho(t, x, e)) \\ = \int \tilde{\sigma}(x, e, e') \rho(t, x, e') de' - \tilde{\Sigma}(x, e) \rho(t, x, e), \end{aligned} \quad (3)$$

where the coefficients D , $\tilde{\sigma}$, $\tilde{\Sigma}$ are non-negative. Of course, one obtains similar systems in the (energy-)discretized context. These equations can be derived directly from a balance relation on the population of neutrons, through a phenomenological analysis of the scattering events. The diffusion coefficients are due to elastic scattering when neutrons do not lose energy during the collision process. Zeroth order terms are due to absorption, inelastic scattering (i.e. collisions with loss of energy) or fission. Furthermore, system (3) can be generalized by postulating that the diffusion operator couples the energy levels as follows

$$\operatorname{div}_x \left(\int k(x, e, e') \nabla_x \rho(t, x, e') de' \right).$$

Indeed, gradients of the density ρ at a given energy e' can have some effect on the diffusion on another energy level e .

However, it is also tempting to obtain systems like (3) from the kinetic modeling, eq. (1-2), and to identify the coefficients through an asymptotic analysis. Then, starting from the continuity equation

$$\partial_t \rho + \operatorname{div}_x j = \int_{S^{N-1}} Q(f) d\omega \quad (4)$$

satisfied by the macroscopic density

$$\rho(t, x, e) = \int_{S^{N-1}} f(t, x, \sqrt{2e/m} \omega) d\omega,$$

and the macroscopic current

$$j(t, x, e) = \int_{S^{N-1}} \sqrt{2e/m} \omega f(t, x, \sqrt{2e/m} \omega) d\omega,$$

we search for a diffusion equation by postulating a relation between ρ and j that takes the form of a generalized Fick's law

$$j(t, x, e) = - \int k(x, e, e') \nabla_x \rho(t, x, e') de'.$$

Such an approximation is intended to apply in the limit of small mean free paths, which is related to the probability of collisions by unit length and decreases when the density of the medium increases. It leads to singular perturbation problems and this work is devoted to such a question.

We refer for details on the physics of nuclear reactors to the classical books of B. Davison [17], E. Wigner [41], E. Wachspress [40], J. Bussac-P. Reuss [12], J. Planchard [37], C.

Cercignani [15]. The mathematical study of the vanishing mean free path limit and of the diffusion approximation is by now a classical problem with applications in various fields of physics; we refer among others to E. Larsen-J. Keller [32], A. Bensoussan-J.-L. Lions-G. Papanicolaou [10], C. Bardos-R. Santos-R. Sentis [8] and, for recent progresses, to R. Dautray-J.L. Lions [16], F. Malvagi-D. Levermore-G. Pomraning [35], F. Poupaud [38], F. Golse [26], C. Bardos-F. Golse-B. Perthame [6], C. Bardos-F. Golse-B. Perthame-R. Sentis [7], F. Golse-F. Poupaud [27], P. L. Lions-G. Toscani [34] P. Degond-T. Goudon-F. Poupaud [20]... Another difficulty in reactor physics is related to the high heterogeneity of the surrounding medium. Accordingly, the cross sections depend on the space variable and present very large oscillations. This leads to homogenization questions. Depending on the ordering, the homogenization procedure can be performed at the kinetic level, see F. Golse [24, 25], L. Dumas-F. Golse [22], P. Gérard-F. Golse [23] or directly on the diffusion approximation as in J. Dorning-R. Uddin-H. Zhang [21] Y. Capdeboscq [13, 14], G. Allaire-Y. Capdeboscq [2], G. Allaire-F. Malige [3]. We can also combine altogether these effects as in E. Larsen [30, 31], E. Larsen-M. Williams [33], C. Bardos-L. Dumas-P. Gérard-F. Golse [5], G. Allaire-G. Bal [1], G. Bal [4], T. Goudon-F. Poupaud [29], T. Goudon-A. Mellet [28].

However, it is a well-known fact that different (formal) methods of approximation can give rise to difference on the limit coefficients, see [31] or [37], [1], [13] for some examples. Furthermore, when starting from multigroup equations and performing the diffusion approximation limit, one usually obtains a single diffusion equation in the space variable only, see [2], [13]: the limit procedure forgets the multigroup aspect. This is because the system is considered to relax towards an equilibrium under both elastic and inelastic collisions at the same scale. However, it could be interesting to derive more complex models, which retain the energy as a variable and where the diffusion as well as the inelastic collisions couple the various energy levels. This is the goal of the present paper. To that purpose, our analysis is inspired by reasonings developed in the modeling of semiconductors devices where, instead of obtaining a drift-diffusion equation, we are led to an intermediate system, by keeping the energy as a variable, see Ben Abdallah-P. Degond [9], P. Degond [18, 19]. We also mention the recent application to the phonons dynamics by J. P. Bourgade [11]. These so-called SHE-models have been shown to be very accurate, in particular for numerical simulations. It is worth noticing at the moment that the energy coupling can be obtained either through the zeroth order terms when the inelastic collisions are treated as perturbations, or through the diffusion operator when inelastic processes are treated in a more intricate way, as it has been done by P. Degond [19], in the framework of semiconductors theory, for continuous energy levels. However, the analysis developed in the present paper, though largely inspired from [19], requires less restrictive hypotheses (see in particular Section 3 and Proposition 5). Note that this work is only concerned with the diffusion approximation problem; the homogenization question will be addressed elsewhere. Note also that we have chosen to treat the evolution problem but, of course, our analysis can be applied to eigenvalue problems as well.

The paper is organized as follows. In Section 2, we will set up precisely the multigroup aspect on the Boltzmann equation. Section 3 is devoted to a discussion of some properties

of the collision operator. In particular, we aim at splitting the Boltzmann operator into an elastic part, that leaves the number of neutrons in a given energy level unchanged, and an inelastic part. This can be done either locally or not as far as the energy variable is concerned. In some sense, the latter retains some relevant information on the energy exchange during the collisions with the medium. In Section 4 we formally discuss the small mean free path asymptotic limit with the requirement that elastic, or quasi-elastic, processes dominate. Actually, our method can be viewed as a heuristic procedure to derive macroscopic models, which are intermediate between a full kinetic description and a simple diffusion equation. Finally, Section 5 is concerned with a rigorous proof of convergence.

2 Multigroup equations

The evolution of the population of neutrons is described through an equation relating transport to interaction processes as follows

$$\begin{cases} (\partial_t + v \cdot \nabla_x) f = Q(f), \\ Q(f) = \frac{1}{|S^{N-1}|} \int_{\mathbb{R}^N} \sigma(x, v, v') f(v') dv' - \Sigma(x, v) f(v), \\ \Sigma(x, v) = \frac{1}{|S^{N-1}|} \int_{\mathbb{R}^N} \sigma(x, v', v) dv'. \end{cases} \quad (5)$$

The third relation means that the operator Q is conservative, or critical, in the sense that, neglecting integrability questions for the time being, we have

$$\int_{\mathbb{R}^N} Q(f) dv = 0.$$

Compared to the Introduction, we have changed the cross-sections by introducing the normalization by $\frac{1}{|S^{N-1}|}$ for pure convenience; it will allow us to work with normalized measure and will simplify some forthcoming computations.

We write the velocity of the particles as follows

$$\begin{cases} v = |v| \omega = \sqrt{2e/m} \omega, \\ \omega = v/|v| = \text{angular variable} \in S^{N-1}, \\ e = mv^2/2 = \text{energy variable} \in \mathbb{R}^+. \end{cases}$$

Denoting by $d\omega$ the normalized Euclidian measure on S^{N-1} , we have $dv = |S^{N-1}| r^{N-1} dr d\omega$, with $r = |v| = \sqrt{2e/m}$, and therefore $dr = \frac{de}{\sqrt{2me}}$. We deduce the following change of variable formula

$$\int_{\mathbb{R}^N} \varphi(v) dv = \int_0^\infty |S^{N-1}| \int_{S^{N-1}} \varphi(\sqrt{2e/m} \omega) (2e/m)^{N/2} \frac{de}{2e} d\omega$$

which applies to any integrable function φ .

Let us discretize the energy levels by introducing the energy step $\varepsilon > 0$ (we point out that ε will remain fixed throughout the paper, and will not tend to zero). We set $E_i = [i\varepsilon, (i+1)\varepsilon[$ and then, we consider

$$f_i(t, x, \omega) = \frac{1}{2\varepsilon} \int_{E_i} f(t, x, \sqrt{2e'/m} \omega) (2e'/m)^{N/2} \frac{de'}{2e'}$$

which will be a new unknown. Equations for the f_i 's are obtained by averaging (5). In the left hand side, we approach v by $v_i = \sqrt{2i\varepsilon/m} \omega$ and the transport term is approximately $(\partial_t + v_i \cdot \nabla_x) f_i$. For the collision term, one has

$$\begin{aligned} & \frac{1}{2\varepsilon} \int_{E_i} Q(f)(t, x, |v|\omega) |v|^N \frac{de}{2e} \\ &= \frac{1}{2\varepsilon} \int_{E_i} \left(\int_0^\infty \int_{S^{N-1}} \sigma(\sqrt{2e'/m} \omega, \sqrt{2e'/m} \omega') f(\sqrt{2e'/m} \omega') (2e'/m)^{N/2} \frac{de'}{2e'} d\omega' \right. \\ & \quad \left. - \int_0^\infty \int_{S^{N-1}} \sigma(\sqrt{2e'/m} \omega', \sqrt{2e/m} \omega) (2e'/m)^{N/2} \frac{de'}{2e'} d\omega' f(\sqrt{2e/m} \omega) \right) (2e/m)^{N/2} \frac{de}{2e} \\ &= \frac{1}{2\varepsilon} \sum_j \int_{E_j} \int_{S^{N-1}} \left(\int_{E_i} \sigma(\sqrt{2e'/m} \omega, \sqrt{2e'/m} \omega') (2e'/m)^{N/2} \frac{de'}{2e'} \right) \\ & \quad f(\sqrt{2e'/m} \omega') (2e'/m)^{N/2} \frac{de'}{2e'} d\omega' \\ & \quad - \frac{1}{2\varepsilon} \int_{E_i} f(\sqrt{2e/m} \omega) \\ & \quad \left(\sum_j \int_{E_j} \int_{S^{N-1}} \sigma(\sqrt{2e'/m} \omega', \sqrt{2e/m} \omega) (2e'/m)^{N/2} \frac{de'}{2e'} d\omega' \right) (2e/m)^{N/2} \frac{de}{2e}. \end{aligned}$$

Then, we suppose that σ does not vary too much as the energy variables (e, e') belong to the set $E_i \times E_j$ and we make the following approximation:

$$\text{For } e' \in E_j, \quad \sigma_{ij}(\omega, \omega') \sim \int_{E_i} \sigma(\sqrt{2e/m} \omega, \sqrt{2e'/m} \omega') (2e/m)^{N/2} \frac{de}{2e},$$

so that $Q(f)$ is replaced by

$$Q(f)_i(\omega) = \sum_j \int_{S^{N-1}} \sigma_{ij}(\omega, \omega') f_j(\omega') d\omega' - \Sigma_i(\omega) f_i(\omega), \quad (6)$$

where

$$\Sigma_i(\omega) = \sum_j \int_{S^{N-1}} \sigma_{ji}(\omega', \omega) d\omega'.$$

These notations lead to the following multigroup kinetic equation

$$(\partial_t + v_i \cdot \nabla_x) f_i = Q(f)_i. \quad (7)$$

REMARK 1 *Of course, the subdomains E_i can be defined by using another discretization rule. For instance, one often discretizes the energy range by means of the lethargy $\lambda(e) = \ln(e_{ref}/e)$ and $E_i = \{e \geq 0, \lambda(e) \in [\lambda_i, \lambda_{i+1}[\}$, see [41].*

3 Splitting of the collision operator

In this section, we introduce two different splittings of the collision operator into elastic and inelastic parts. Here and below "elastic" means that the operator leaves invariant the total number of neutrons on a given energy level. As in [19], we will see that it is relevant to use a convex combination of these splittings. For convenience, we skip the space dependence, having in mind that the estimates discussed below are uniform with respect to x . Besides, we shall only state precisely the assumptions on the cross-sections σ_{ij} and the properties of the collision operators that will be necessary later on; proofs are postponed into the appendix.

3.1 First splitting

Let us split the collision operator (6) as follows

$$\begin{aligned} Q(f)_i(\omega) &= \sum_j \int_{S^{N-1}} \left(\sigma_{ij}(\omega, \omega') f_j(\omega') - \sigma_{ji}(\omega', \omega) f_i(\omega') \right) d\omega' \\ &+ \int_{S^{N-1}} \left(\sum_j \sigma_{ji}(\omega', \omega) \right) \left(f_i(\omega') - f_i(\omega) \right) d\omega'. \end{aligned} \quad (8)$$

The first operator modifies energy while angle remains unchanged, thus, we refer to it as the inelastic part, denoted by Q_0^{inel} ; the second operator modifies the velocity direction while energy is conserved, thus, we called it the elastic part, denoted by Q_0^{el} . Let us set

$$\Gamma_i(\omega', \omega) = \sum_j \sigma_{ji}(\omega', \omega), \quad \Sigma_i(\omega) = \int_{S^{N-1}} \Gamma_i(\omega', \omega) d\omega'$$

then we have

$$Q_0^{el}(f)_i = \int_{S^{N-1}} \Gamma_i(\omega', \omega) (f_i(\omega') - f_i(\omega)) d\omega' = K(f)_i - \Sigma_i f_i.$$

Let us now state the first assumptions concerning the kernel $\sigma_{ij}(\omega, \omega')$:

$$(h1) \quad \text{First symmetry assumption: } \Sigma_i(\omega) = \int_{S^{N-1}} \Gamma_i(\omega', \omega) d\omega' = \int_{S^{N-1}} \Gamma_i(\omega, \omega') d\omega'.$$

In order to derive the coercivity properties of the operator Q_0^{el} , we also require the following hypothesis:

$$(h2) \quad \begin{cases} \text{There exists a sequence of positive reals } (\gamma_i)_{i \in \mathbb{N}} \\ \text{and a constant } M_0 \text{ such that } \gamma_i \leq \Gamma_i(\omega', \omega) \leq M_0 \gamma_i. \end{cases}$$

For technical purposes now, we introduce a sequence $(B_i)_{i \in \mathbb{N}}$ of positive numbers, satisfying:

$$(h3) \quad \text{Weight assumption: } (B_i)_{i \in \mathbb{N}} \text{ is such that } \sum_i B_i \gamma_i = M_1 < \infty,$$

(it is easy to check that such a sequence always exists). Note that (h2) and (h3) yield

$$\sum_i B_i \int_{S^{N-1}} \Sigma_i(\omega) d\omega \leq M_0 M_1.$$

It is worth having in mind the following simple example of the isotropic Boltzmann equation, with typically $B_i = e^{-i}$,

$$\sigma_{ij}(\omega, \omega') = c_i c_j B_i, \quad c_i B_i \in \ell^1. \quad (9)$$

This leads to $\Gamma_i(\omega, \omega') = \|cB\|_{\ell^1} c_i$ and (h2) is fulfilled with $M_0 = \|cB\|_{\ell^1}^2$, and $\gamma_i = c_i$.

We now introduce the following functional spaces

$$\begin{aligned} \mathbb{E} &= \left\{ f : \mathbb{N} \times S^{N-1} \rightarrow \mathbb{R} \text{ such that } \|f\|_{\mathbb{E}}^2 = \sum_i \int_{S^{N-1}} |f_i(\omega)|^2 \frac{\Sigma_i(\omega)}{B_i} d\omega < \infty \right\}, \\ \mathbb{F} &= \left\{ f : \mathbb{N} \times S^{N-1} \rightarrow \mathbb{R} \text{ such that } \|f\|_{\mathbb{F}}^2 = \sum_i \int_{S^{N-1}} |f_i(\omega)|^2 \frac{1}{\Sigma_i(\omega) B_i} d\omega < \infty \right\}. \end{aligned}$$

We shall identify the space

$$\mathbb{L} = \left\{ f : \mathbb{N} \times S^{N-1} \rightarrow \mathbb{R} \text{ such that } \|f\|_{\mathbb{L}}^2 = \sum_i \int_{S^{N-1}} |f_i(\omega)|^2 \frac{1}{B_i} d\omega < \infty \right\}$$

with its dual when equipped with the inner product

$$(f, g)_{\mathbb{L}} = \sum_i \int_{S^{N-1}} f_i(\omega) g_i(\omega) \frac{1}{B_i} d\omega.$$

Consequently, we note that

$$\left| \sum_i \int_{S^{N-1}} f_i(\omega) g_i(\omega) \frac{1}{B_i} d\omega \right| \leq \|f\|_{\mathbb{E}} \|g\|_{\mathbb{F}}$$

for any $f \in \mathbb{E}$, $g \in \mathbb{F}$ and we can identify \mathbb{F} with the dual \mathbb{E}' . We are now ready to establish the main properties of the elastic operator Q_0^{el} .

PROPOSITION 1 *Assume that (h1) holds. Then, $Q_0^{el} \in \mathcal{L}(\mathbb{E}, \mathbb{F})$ with $\|Q_0^{el}(f)\|_{\mathbb{F}} \leq 2\|f\|_{\mathbb{E}}$, and we have*

i) Conservation property: $\int_{S^{N-1}} Q_0^{el}(f)_i d\omega = 0$ (at least formally; see Remark 3),

ii) *Dissipativity property:* for all f, g in \mathbb{E} , we set $\mathcal{B}_0(f, g) = -\sum_i \int_{S^{N-1}} Q_0^{el}(f)_i g_i B_i^{-1} d\omega$.

Then, \mathcal{B}_0 is bilinear continuous on \mathbb{E} and satisfies

$$\begin{aligned} \mathcal{B}_0(f, f) &= 1/2 \sum_i \int_{S^{N-1}} \int_{S^{N-1}} \Gamma_i(\omega', \omega) |f_i(\omega) - f_i(\omega')|^2 B_i^{-1} d\omega' d\omega \\ &\geq 1/2 \|Q_0^{el}(f)\|_{\mathbb{F}}^2. \end{aligned}$$

iii) *The eigenspace $\text{Ker}(Q_0^{el})$ is the space \mathcal{E}_0 of functions in \mathbb{E} which do not depend on the angular variable.*

REMARK 2 *Under Hypothesis (h2), one remarks that $\mathcal{E}_0 = \{f : \mathbb{N} \rightarrow \mathbb{R}, \sum_i f_i^2 \gamma_i B_i^{-1} < \infty\}$ does not reduce to $\{0\}$. For instance, with (h2)-(h3) it contains $\{f_i = B_i g_i, g \in \ell^\infty\} \subset \mathcal{E}_0$. Indeed, for such a f , we get*

$$0 \leq \sum_i \int_{S^{N-1}} \Sigma_i f_i^2 / B_i d\omega = \sum_i \left(g_i^2 B_i \int_{S^{N-1}} \Sigma_i d\omega \right) \leq M_1 M_0 \|g\|_{\ell^\infty}^2 < \infty.$$

When taking into account time and space variable we will work with sequences of functions $f_i(t, x)$ that satisfy the corresponding integrability condition.

REMARK 3 *Assumption (h3) also implies that \mathbb{F} is a subset of integrable functions, for the measure $d\omega \otimes di$, where di is the counting measure on \mathbb{N} , since one has*

$$\sum_i \int_{S^{N-1}} |g_i| d\omega \leq \left(\sum_i \int_{S^{N-1}} g_i^2 / (B_i \Sigma_i) d\omega \right)^{1/2} \left(\sum_i \int_{S^{N-1}} B_i \Sigma_i d\omega \right)^{1/2} \leq \|g\|_{\mathbb{F}} (M_0 M_1)^{1/2}.$$

A similar conclusion holds for $f \in \mathbb{E}$ if one assumes

$$\sum_i \int_{S^{N-1}} B_i / \Sigma_i d\omega < \infty.$$

For (9), this means that $B/c \in \ell^1$.

In order to state a coercivity property in a useful setting, we introduce the following norm

$$N(f) = \sum_i \int_{S^{N-1}} |f_i(\omega)|^2 \frac{\gamma_i}{B_i} d\omega.$$

In view of Hypothesis (h2), it is readily seen that $N(f)$ defines an equivalent norm on \mathbb{E} . Actually we have

$$N(f)^2 \leq \|f\|_{\mathbb{E}}^2 \leq M_0 N(f)^2.$$

COROLLARY 1 *Under Hypotheses (h1-h3), the following coercivity estimate*

$$\mathcal{B}_0(f, f) \geq N^2(f - \langle f \rangle)$$

holds for any $f \in \mathbb{E}$, where one denotes $\langle f \rangle_i = \int_{S^{N-1}} f_i(\omega) d\omega$.

REMARK 4 *The adjoint operator of Q_0^{el} reads*

$$\begin{aligned} Q_0^{el,*}(g)_i &= \int_{S^{N-1}} \Gamma_i(\omega, \omega') g_i(\omega') d\omega' - \Sigma_i(\omega) g_i(\omega) \\ &= \int_{S^{N-1}} \Gamma_i(\omega, \omega') (g_i(\omega') - g_i(\omega)) d\omega'. \end{aligned}$$

3.2 Second splitting

On the other hand, we can also introduce the following splitting into elastic and inelastic operators

$$Q(f)_i = Q_1^{el}(f)_i + Q_1^{inel}(f)_i$$

with

$$\begin{cases} Q_1^{el}(f)_i = \sum_j \int_{S^{N-1}} \sigma_{ij}(\omega, \omega') (f_j(\omega') - f_j(\omega)) d\omega' \\ Q_1^{inel}(f)_i = \sum_j \left(\int_{S^{N-1}} \sigma_{ij}(\omega, \omega') d\omega' f_j(\omega) \right) - f_i(\omega) \sum_j \int_{S^{N-1}} \sigma_{ji}(\omega', \omega) d\omega' \end{cases} \quad (10)$$

The boundedness of Q_1^{el} relies on the following assumption

$$(h4) \quad \begin{cases} \text{There exists a constant } M_2 \text{ such that} \\ \sum_j \int_{S^{N-1}} \sigma_{ij}(\omega, \omega') B_j d\omega' \leq M_2 \gamma_i B_i \end{cases}$$

It is worth pointing out that this assumption is a straightforward consequence of (h2-h3), if we assume the following relation, known as the detailed balance principle

$$\sigma_{ij}(\omega, \omega') B_j = \sigma_{ji}(\omega', \omega) B_i. \quad (11)$$

We also need the

$$(h1') \quad \text{Second symmetry condition: } \int_{S^{N-1}} \sigma_{ij}(\omega', \omega) d\omega' = \int_{S^{N-1}} \sigma_{ij}(\omega, \omega') d\omega'.$$

Remark that (h1') is stronger than (h1), and that (h4) as well as (h2) are fulfilled if we assume $\sigma_{ij} \leq M \gamma_i B_i \gamma_j$.

PROPOSITION 2 *Assume that (h1', h2, h3, h4) hold. Then, $Q_1^{el} \in \mathcal{L}(\mathbb{E}, \mathbb{F})$ with $\|Q_1^{el}(f)\|_{\mathbb{F}} \leq 2M_2^{1/2}\|f\|_{\mathbb{E}}$, and we have*

i) *Conservation property:*
$$\int_{S^{N-1}} Q_1^{el}(f)_i d\omega = 0,$$

ii) *For all f, g we set $\mathcal{B}_1(f, g) = -\sum_i \int_{S^{N-1}} Q_1^{el}(f)_i g_i B_i^{-1} d\omega$. Then, \mathcal{B}_1 is bilinear continuous on \mathbb{E} and it satisfies*

$$\mathcal{B}_1(f, g) = \frac{1}{2} \sum_{i,j} \int_{S^{N-1}} \int_{S^{N-1}} (f_j(\omega') - f_j(\omega)) (\sigma_{ij}(\omega', \omega) g_i(\omega') - \sigma_{ij}(\omega, \omega') g_i(\omega)) B_i^{-1} d\omega' d\omega.$$

iii) $\mathcal{E}_0 \subset \text{Ker}(Q_1^{el})$, and the following estimate holds

$$|\mathcal{B}_1(f, f)| \leq M_0 \sqrt{2M_2} N(f - \langle f \rangle)^2.$$

Of course functions depending only on the energy variable belongs to $\text{Ker}(Q_1^{el})$; however, the kernel of Q_1^{el} contains much more functions. Note that iii) is slightly sharper than the estimate obtained by using the norm of Q_1^{el} ; it can be improved under more restrictive assumptions on the kernels.

COROLLARY 2 *Under the*

$$(h1'') \quad \text{Strong symmetry assumption: } \sigma_{ij}(\omega, \omega') = \sigma_{ij}(\omega', \omega)$$

and

$$(h2'') \quad \sigma_{ij}(\omega, \omega') \leq M \gamma_i B_i \gamma_j \quad \text{with } \sum_i B_i \gamma_i = M_1 < \infty,$$

the operator Q_0^{el} is self-adjoint and, concerning Q_1^{el} , we have

$$\mathcal{B}_1(f, g) = 1/2 \sum_{i,j} \int_{S^{N-1}} \int_{S^{N-1}} \sigma_{ij}(\omega, \omega') (f_j(\omega') - f_j(\omega)) (g_i(\omega') - g_i(\omega)) B_i^{-1} d\omega' d\omega.$$

As a consequence, if $\langle f \rangle = 0$, then iii) becomes

$$|\mathcal{B}_1(f, f)| \leq MM_1 N(f)^2.$$

REMARK 5 *Notice that (h1'') implies (h1') while (h2'') implies both (h2) and (h3) with $M_0 = MM_1$, and (h4) with $M_2 = M_1$. The bound from below in (h2) is fulfilled if one assumes a similar estimate from below on the σ_{ij} 's.*

REMARK 6 *The previous symmetry conditions are included in*

$$\sigma_{ij}(\omega, \omega') B_j = \sigma_{ij}(\omega', \omega) B_j = \sigma_{ji}(\omega', \omega) B_i = \sigma_{ji}(\omega, \omega') B_i \quad (12)$$

which also implies that Q_1^{el} is self-adjoint. This corresponds to the symmetry assumption used in [19]; but here we aim at dealing with a larger class of collision kernels.

Let us go back to the fundamental example (9). Denote $C = \sum_i c_i B_i < \infty$. One has in this simple case

$$\begin{cases} Q_0^{el}(f)_i = C c_i (\langle f_i \rangle - f_i), \\ Q_1^{el}(f)_i = c_i B_i \sum_j c_j (\langle f_j \rangle - f_j). \end{cases}$$

Therefore, we get

$$\begin{cases} B_0(f, g) = \sum_{i,j} c_i B_i^{-1} c_j B_j (\langle f_i \rangle \langle g_i \rangle - \langle f_i g_i \rangle), \\ B_1(f, g) = \sum_{i,j} c_i c_j (\langle f_j \rangle \langle g_i \rangle - \langle f_j g_i \rangle). \end{cases}$$

We write $g_i = \langle g_i \rangle + r_i$ where $\langle r_i \rangle = 0$. It yields

$$\begin{aligned} B_1(f, g) &= \sum_{i,j} c_i c_j (\langle f_j \rangle \langle g_i \rangle - \langle f_j \rangle \langle g_i \rangle - \langle f_j r_i \rangle) \\ &= - \sum_{i,j} c_i c_j \langle f_j r_i \rangle = - \sum_{i,j} c_i c_j \int_{S^{N-1}} f_j r_i d\omega \\ &= - \int_{S^{N-1}} \left(\sum_j c_j f_j \right) \left(\sum_i c_i r_i \right) d\omega. \end{aligned}$$

If g lies in the orthogonal set of $\text{Ran}(Q_1^{el})$, we deduce that $\sum_i c_i r_i(\omega)$ vanishes for almost all $\omega \in S^{N-1}$.

REMARK 7 *The adjoint operator of Q_1^{el} is given by:*

$$Q_1^{el,*}(g)_i = \sum_j \int_{S^{N-1}} \sigma_{ji}(\omega', \omega) (g_j(\omega') - g_j(\omega)) \frac{B_i}{B_j} d\omega'.$$

In particular, we note that, if the relation (11) holds, then Q_1^{el} is a self-adjoint operator.

3.3 Combination of the splitting

From now on, we assume that (h1'), (h2), (h3), (h4) hold and we denote by (H) this set of hypotheses. The idea will be to combine Q_1^{el} with Q_0^{el} so that the coercivity of the latter compensates the lack of positivity of the former; we are thus able to preserve the crucial dissipation properties. Let us consider the following elastic operator, obtained as a convex combination of Q_0^{el} and Q_1^{el} ; for $\theta \in [0, 1]$, we set

$$Q_\theta = \theta Q_1^{el} + (1 - \theta) Q_0^{el}.$$

One deduces from Corollary 1 and Proposition 2 that

$$B_\theta(f, f) = - \sum_i \int_{S^{N-1}} Q_\theta(f)_i f_i B_i^{-1} d\omega \geq (1 - \theta(1 + M_0 \sqrt{2M_2})) N(f - \langle f \rangle)^2$$

holds for any $f \in \mathbb{E}$. We are thus led to the following statement.

PROPOSITION 3 *Let $\theta \in [0, (1 + M_0\sqrt{2M_2})^{-1}]$. Then, there exists a constant $\kappa_\theta > 0$ such that, for any $f \in \mathbb{E}$, we have*

$$\mathcal{B}_\theta(f, f) \geq \kappa_\theta N(f - \langle f \rangle)^2.$$

Consequently, the set of equilibria $\mathcal{E}_\theta = \text{Ker}(Q_\theta)$ coincides with \mathcal{E}_0 (the set of functions depending only on the energy level). If one assumes (h1") and (h2"), the domain for θ enlarges to $[0, (1 + M_0)^{-1}]$.

One may also establish the following Fredholm alternative.

PROPOSITION 4 *For any $h \in \mathbb{F}$ the problem to find $f \in \mathbb{E}$ such that $Q_\theta(f) = h$ has a solution if and only if $\langle h \rangle = 0$. The solution is unique in $\mathbb{E}_0 = \{f \in \mathbb{E} \text{ such that } \langle f \rangle = 0\}$ and satisfies*

$$N(f) \leq (1/\sqrt{\kappa_\theta}) \|h\|_{\mathbb{F}}.$$

Proof. Since the operator Q_θ is clearly conservative, the condition of null average on the data h is necessary. The problem recasts into the following variational formulation

$$\forall \varphi \in \mathbb{E}_0, \quad \mathcal{B}_\theta(f, \varphi) = \sum_i \int_{S^{N-1}} h_i \varphi_i B_i^{-1} d\omega = (h, \varphi)_{\mathbb{L}}$$

and we conclude by applying the Lax-Milgram theorem. \square

Of course, one has a similar statement for the adjoint operator: Q_θ^* is defined by

$$Q_\theta^* = \theta Q_1^{el,*} + (1 - \theta) Q_0^{el,*},$$

and fulfills the same coercivity property as Q_θ with the same constant of coercivity, since

$$\mathcal{B}_\theta(f, f) = - \sum_i \int_{S^{N-1}} Q_\theta^*(f)_i f_i B_i^{-1} d\omega.$$

Therefore we have

COROLLARY 3 *For any $h \in \mathbb{F}$ there exists $f \in \mathbb{E}$ such that $Q_\theta^*(f) = h$ if and only if $\langle h \rangle = 0$. Moreover, there exists a unique such function in $\mathbb{E}_0 = \{f \in \mathbb{E} \text{ such that } \langle f \rangle = 0\}$, and this solution satisfies*

$$N(f) \leq (1/\sqrt{\kappa_\theta}) \|h\|_{\mathbb{F}}.$$

4 Formal approach

The starting point of the asymptotic study is the following rescaled equation

$$\partial_t f_i^\eta + \frac{1}{\eta} v_i \cdot \nabla_x f_i^\eta = \frac{1}{\eta^2} (Q^\eta(f^\eta))_i. \quad (13)$$

Precisely, we consider the situation where the mean free path $\eta > 0$ is small at time scale of order $1/\eta$. On the other hand, we assume that the collision operator Q^η splits as follows

$$Q^\eta(f) = Q_\theta(f) + \eta^2 Q_\theta^{inel}(f),$$

which means that inelastic collisions are of order η^2 compared to the elastic ones. This agrees with the fact that dominant scattering events are elastic. Of course, in this splitting θ is fixed and cannot be too small compared to η . In particular, it is also required that θ belongs to the range which guarantees the coercivity of the operator Q_θ , see Proposition 3. Our aim is to describe the asymptotic behaviour of the solutions of (13) as $\eta \rightarrow 0$. We will obtain a set of diffusion equations, which can be viewed as a semi-discrete (with respect to the energy) version of the SHE-system of [19], for the limit macroscopic density with a coupling of the energy levels due to the action of the operator Q_1^{el} and/or the inelastic terms.

4.1 Formal Hilbert expansion

We can guess the limit behaviour by inserting the formal ansatz

$$f^\eta = f^0 + \eta f^1 + \eta^2 f^2 + \dots$$

into (13) and then, we identify the terms that arise with the same power of η . As usual, the η^{-2} terms lead to

$$Q_\theta(f^0) = 0$$

which means, by Proposition 3, that $(f^0)_i(\omega) = \rho_i \in \mathcal{E}_0$ does not depend on the angular variable. Hence, one expects that the asymptotic limit is entirely determined in terms of "macroscopic" quantities. Next, the η^{-1} equation reads

$$Q_\theta(f^1) = v \cdot \nabla_x \rho,$$

while the η^0 equation is

$$Q_\theta(f^2) + Q_\theta^{inel}(\rho) = v \cdot \nabla_x f^1 + \partial_t \rho.$$

Integrating with respect to ω , we are led to the following relation

$$\partial_t \rho_i + \operatorname{div}_x \left(\int_{S^{N-1}} \sqrt{2e_i/m} \omega f_i^1(\omega) d\omega \right) = \int_{S^{N-1}} Q_\theta^{inel}(\rho) d\omega. \quad (14)$$

The usual strategy consists in inverting the η^{-1} equation; one expects in this way to determine the current $\int_{S^{N-1}} \sqrt{2e_i/m} \omega f_i^1(\omega) d\omega$ in the previous equation as a linear function of $\nabla_x \rho$, i.e. a Fick's relation. The difficulty of this method here comes from the action of the operator Q_1^{el} which mixes the energy levels. In particular, if ρ_i depends only on the energy and $f_i(\omega)$ depends on the two variables, in general one has

$$\begin{aligned} Q_1(\rho f)_i &= \sum_j \int_{S^{N-1}} \sigma_{ij}(\omega, \omega') \rho_j (f_j(\omega') - f_j(\omega)) d\omega' \\ &\neq \rho_i Q_1(f)_i = \rho_i \sum_j \int_{S^{N-1}} \sigma_{ij}(\omega, \omega') (f_j(\omega') - f_j(\omega)) d\omega' \end{aligned}$$

(while $Q_0(\rho f)_i = \rho_i Q_0(f)_i$). However, we can solve the problem as follows. Let us define $\bar{\chi}^i \in (\mathbb{E}_0)^N$ solution of

$$Q_\theta(\bar{\chi}^i)_{i_0} = -v_{i_0} \delta_{i_0 i},$$

where $\delta_{i_0 i} = 1$ if $i = i_0$, and 0 if $i \neq i_0$. The equation has to be understood componentwise, and this definition makes sense thanks to Proposition 4 (since $\int_{S^{N-1}} \omega d\omega = 0$). Then one checks that

$$f_{i_0}^1 = \sum_i \bar{\chi}_{i_0}^i \cdot \nabla_x \rho_i$$

provides a solution to the η^{-1} equation. Plugging this expression into (14) gives

$$\begin{cases} \partial_t \rho_{i_0} - \nabla_x \left(\sum_i D_{i_0 i} \nabla_x \rho_i \right) = q(\rho)_{i_0}, \\ q(\rho)_{i_0} = \int_{S^{N-1}} [Q_\theta^{inel}(\rho)]_{i_0} d\omega, \\ D_{i_0 i} = - \int_{S^{N-1}} v_{i_0} \otimes \bar{\chi}_{i_0}^i d\omega \end{cases}$$

where \otimes stands for the tensor product in \mathbb{R}^N : for (a_1, \dots, a_N) and (b_1, \dots, b_N) in \mathbb{R}^N , $a \otimes b$ is the $N \times N$ matrix with components $a_\alpha b_\beta$. We observe in the limit equation a coupling between the energy levels, both from the diffusion matrix and from the right hand side.

A possible strategy to justify these computations would be to start from a solution ρ of the expected limit equation (which has to be studied independently), and to define successively f^1, f^2 in terms of ρ as solutions of the η^{-1} and η^0 equations respectively. It remains to estimate the remainder $r^\eta = f^\eta - (\rho + \eta f^1 + \eta^2 f^2)$. The drawback of this method is that it is known to require some regularity on ρ , thus on the coefficients. Such an assumption can be unrealistic for neutron transport since the physical properties of the media interacting with the neutrons are usually highly heterogeneous. On the other hand, it could be quite delicate to carry out this strategy in the full generality considered here. Therefore, let us instead develop a duality approach, which will be close to our actual method of proof.

4.2 Duality interpretation

Let us assume that f^η converges to some f^0 in a suitable sense. Multiplying by η^2 and taking the limit $\eta \rightarrow 0$ in (13), we recover

$$Q_\theta(f^0)_i = 0, \quad \forall i \in \mathbb{N},$$

and thus $f_i^0(t, x, \omega) = \rho_i(t, x)$.

We introduce the following macroscopic quantities

$$\begin{cases} \text{density of } i\text{th energy level} & \rho_i^\eta(t, x) = \int_{S^{N-1}} f_i^\eta(t, x, \omega) d\omega, \\ \text{current of } i\text{th energy level} & J_i^\eta(t, x) = \frac{1}{\eta} \int_{S^{N-1}} |v_i| \omega f_i^\eta(t, x, \omega) d\omega. \end{cases} \quad (15)$$

In view of the penalization of the collision term, one expects that f^η tends to belong to the kernel of Q_θ , therefore it is mainly given by its macroscopic part ρ^η , up to a formally small remainder. Hence, let us write a first order expansion of f^η as follows

$$f_i^\eta(t, x, \omega) = \rho_i^\eta(t, x) + \eta g_i^\eta(t, x, \omega)$$

so that $\rho^\eta \in \text{Ker}(Q_\theta)$ and

$$J_i^\eta(t, x) = \int_{S^{N-1}} |v_i| \omega g_i^\eta(t, x, \omega) d\omega.$$

Integrate equation (13) with respect to ω . Since the operator Q_θ has null average on S^{N-1} , we get for all $i \in \mathbb{N}$:

$$\partial_t \rho_i^\eta + \nabla_x \cdot J_i^\eta = \int_{S^{N-1}} Q_\theta^{inel}(f^\eta)_i d\omega,$$

which is the η -dependent version of the integrated η^0 equation in the formal expansion above. As η goes to 0, we are formally led to the continuity equation

$$\partial_t \rho_i + \nabla_x \cdot J_i = \int_{S^{N-1}} Q_\theta^{inel}(\rho)_i d\omega.$$

It remains to find the relation between the limit current J and ρ .

Multiply (13) by some $\eta \varphi_i(\omega)$. We get

$$\sum_i \frac{1}{\eta} \int_{S^{N-1}} Q_\theta(f^\eta)_i \varphi_i d\omega = \sum_i \int_{S^{N-1}} (v \cdot \nabla_x f^\eta)_i \varphi_i d\omega + \eta \sum_i \int_{S^{N-1}} \partial_t f_i^\eta \varphi_i d\omega,$$

and therefore

$$\sum_i \int_{S^{N-1}} Q_\theta(g^\eta)_i \varphi_i d\omega = \sum_i \left(\int_{S^{N-1}} |v_i| \omega \varphi_i d\omega \right) \cdot \nabla_x \rho_i^\eta + R^\eta, \quad (16)$$

where R^η is formally of order $\mathcal{O}(\eta)$.

Suppose that, for i_0 fixed in \mathbb{N} , we are able to find the auxiliary function $B_i \chi_i^{i_0}(\omega) \in (\mathbb{E}_0)^N$, that solves

$$Q_\theta^*(B \cdot \chi^{i_0})_i = v_{i_0} B_{i_0} \delta_{i_0 i} = \sqrt{2e_{i_0}/m} B_{i_0} \omega \delta_{i_0 i}. \quad (17)$$

Since v_{i_0} lies in \mathbb{R}^N , equation (17) holds for the N scalar equations with right hand sides ω_α for $\alpha \in \{1, \dots, N\}$. Remarking that

$$\int_{S^{N-1}} \omega d\omega = 0,$$

the existence of χ^{i_0} is given by Corollary 3.

Hence, for the test function $\varphi_i(\omega)$, we choose the components of $\chi_i^{i_0}(\omega)$ and (16) becomes

$$\sum_i \int_{S^{N-1}} g_i^\eta Q_\theta^*(B\chi^{i_0})_i B_i^{-1} d\omega = \sum_i \left(\int_{S^{N-1}} |v_i| \chi_i^{i_0} \otimes \omega d\omega \right) \cdot \nabla_x \rho_i^\eta + \mathcal{O}(\eta), \quad (18)$$

with

$$\begin{aligned} \sum_i \int_{S^{N-1}} g_i^\eta Q_\theta^*(B\chi^{i_0})_i B_i^{-1} d\omega &= \sum_i \int_{S^{N-1}} g_i^\eta \sqrt{2e_{i_0}/m} \omega \delta_{i_0 i} d\omega \\ &= \sqrt{2e_{i_0}/m} \int_{S^{N-1}} \omega g_{i_0}^\eta d\omega \\ &= J_{i_0}^\eta. \end{aligned}$$

Here, we used the following fact

$$\sum_i \int_{S^{N-1}} Q_\theta(g^\eta)_i \chi_i^{i_0} d\omega = (Q_\theta(g^\eta), B\chi^{i_0})_{\mathbb{L}} = \sum_i \int_{S^{N-1}} g_i^\eta Q_\theta^*(B\chi^{i_0})_i B_i^{-1} d\omega.$$

Thus, passing to the limit $\eta \rightarrow 0$ in (18), we are led to

$$J_{i_0}(t, x) = - \sum_i D_{i_0 i} \nabla_x \rho_i(t, x) \quad (19)$$

where the matrix D is defined through the auxiliary function χ by

$$D_{i_0 i} = -|v_i| \int_{S^{N-1}} \chi_i^{i_0} \otimes \omega d\omega \in \mathcal{M}_{N \times N}, \quad (20)$$

where $\mathcal{M}_{N \times N}$ stands for the space of $N \times N$ matrices.

The formal limit of (13) is therefore the following macroscopic equation

$$\partial_t \rho - \nabla_x \cdot (D(x) \nabla_x \rho) = q(\rho), \quad (21)$$

where the unknown is the sequence $\rho(t, x) = \{\rho_i(t, x), i \in \mathbb{N}\}$, D is given by (17), (20) and the right hand side by

$$q(\rho)_i = \int_{S^{N-1}} Q_\theta^{inel}(\rho)_i d\omega = \sum_j \Lambda_{ij} \rho_j - \tilde{\Sigma}_i \rho_i, \quad (22)$$

with

$$\begin{cases} \Lambda_{ij} = \int_{S^{N-1}} \int_{S^{N-1}} \sigma_{ij}(\omega, \omega') d\omega d\omega', \\ \tilde{\Sigma}_i = \sum_j \int_{S^{N-1}} \int_{S^{N-1}} \sigma_{ji}(\omega', \omega) d\omega d\omega' = \sum_j \Lambda_{ji}. \end{cases}$$

It is also worth splitting the matrix D as follows. The properties discussed on Q_0^{el} allows us to define a unique $\varphi^{i_0}(\omega) \in \mathbb{R}^N$ verifying

$$(1 - \theta) Q_0^*(B \cdot \varphi^{i_0} \delta_{i_0 \cdot})_i = v_{i_0} B_{i_0} \delta_{i_0 i},$$

with $\int_{S^{N-1}} \varphi^{i_0}(\omega) d\omega = 0$. Then, we split $\chi_i^{i_0} = \varphi^{i_0} \delta_{i_0 i} + \bar{\chi}_i^{i_0}$, where

$$Q_\theta^*(B, \bar{\chi}^{i_0})_i = -\theta Q_1^*(B, \varphi^{i_0} \delta_{i_0 \cdot})_i.$$

In this way, we can rewrite

$$\begin{cases} D_{i_0 i} = d_{i_0} \delta_{i_0 i} + \Delta_{i_0 i}, \\ d_{i_0} = -|v_{i_0}| \int_{S^{N-1}} \varphi^{i_0} \otimes \omega d\omega, \\ \Delta_{i_0 i} = -|v_i| \int_{S^{N-1}} \bar{\chi}_i^{i_0} \otimes \omega d\omega. \end{cases}$$

Hence, one gets $[D\nabla_x \rho]_{i_0} = d_{i_0} \nabla_x \rho_{i_0} + \sum_i \Delta_{i_0 i} \nabla_x \rho_i$. Of course, we can verify readily that this definition of the diffusion matrix coincides with the one obtained in the previous Section.

This limit equation (21) appears as a semi-discrete (in energy) SHE-model with a coupling of the energy levels. Actually, one obtains a hierarchy of possible limit systems:

- A system of uncoupled diffusion equations with respect to the space variable, energy being only a parameter. This arises when inelastic terms are negligible and $\theta = 0$.
- A system of diffusion equations with a coupling of the energy levels through zeroth order terms. This arises with $\theta = 0$ and treating inelastic processes as a perturbation. Diffusivity remains locally defined (with respect to energy) and the coupling describes gain/loss at a given energy level due to inelastic collisions.
- A system of diffusion equations with a strong coupling, from both zeroth order terms and diffusion currents which are now non local: energy exchanges during the collisions induce diffusive effects.

4.3 Fundamental properties of the diffusivity

We are naturally led to discuss some properties of the diffusivity D . To this end, one introduces the following Hilbert space of vector-valued sequences

$$\mathbb{H} = \left\{ \Phi : \mathbb{N} \rightarrow \mathbb{R}^N ; \sum_i |\Phi_i|^2 \frac{2\varepsilon_i}{m\gamma_i B_i} < +\infty \right\}.$$

We shall identify $\ell = \{\Phi : \mathbb{N} \rightarrow \mathbb{R}^N, \sum_i |\Phi_i|^2 B_i^{-1} < \infty\}$ with its dual; accordingly, the dual of \mathbb{H} reads

$$\mathbb{H}' = \left\{ J : \mathbb{N} \rightarrow \mathbb{R}^N ; \sum_i |J_i|^2 \frac{m\gamma_i}{2\varepsilon_i B_i} < +\infty \right\},$$

with the duality relation

$$\langle J, \Phi \rangle_{\mathbb{H}', \mathbb{H}} = \left(J \sqrt{\frac{m c_i}{2\varepsilon_i}}, \Phi \sqrt{\frac{2\varepsilon_i}{m c_i}} \right)_\ell = \sum_i J_i \Phi_i B_i^{-1}.$$

LEMMA 1 *Assume (H). Let us set*

$$\mathcal{D}(\Psi, \Phi) = \sum_{i,j} D_{ij} \Psi_j \cdot \Phi_i B_i^{-1} \quad \forall \Phi, \Psi \in \mathbb{H}.$$

Then,

(i) \mathcal{D} is a bilinear continuous form on \mathbb{H} ;

(ii) \mathcal{D} is positive-definite (symmetric as soon as Q_θ is a self adjoint operator). Furthermore, there exists a constant $c > 0$ such that for all $\Phi \in \mathbb{H}$,

$$\mathcal{D}(\Phi, \Phi) \geq c \|\Phi\|_{\mathbb{H}}^2.$$

Proof. Assuming (H), one associates to Φ in the weighted ℓ^2 space \mathbb{H} , the function

$$\begin{aligned} \phi : \mathbb{N} \times S^{N-1} &\longrightarrow \mathbb{R} \\ (i, \omega) &\longmapsto \phi_i(\omega) = v_i \cdot \Phi_i = \omega \cdot \sqrt{2\epsilon i/m} \Phi_i. \end{aligned}$$

One remarks that ϕ lies in \mathbb{F}_0 , and $\|\phi\|_{\mathbb{F}}$ provides a norm equivalent to the natural norm on \mathbb{H} (by using (h2)). Therefore, Proposition 4 allows us to define the mapping

$$\begin{aligned} K : \mathbb{H} &\longrightarrow \mathbb{E}_0 \\ \Phi &\longmapsto K^\Phi, \end{aligned}$$

with $Q^*(K^\Phi)_i(\omega) = v_i \cdot \Phi_i = \phi_i(\omega)$ i.e. $K^\Phi = Q^{*-1}(\phi)$. Clearly, K is a bounded linear operator from \mathbb{H} to \mathbb{E} .

With these notations, we have the following relation, which will be proved later on,

$$B_j^{-1} K_j^\Phi(\omega) = \sum_i \chi_j^i(\omega) \cdot \Phi_i B_i^{-1}. \quad (23)$$

From the definition of D_{ij} , and (23), we can rewrite \mathcal{D} as follows:

$$\begin{aligned} \mathcal{D}(\Psi, \Phi) &= \sum_{ij} D_{ij} \Psi_j \cdot \Phi_i B_i^{-1} = - \sum_{ij} \int_{S^{N-1}} \chi_j^i(\omega) \cdot \Phi_i B_i^{-1} v_j \cdot \Psi_j d\omega \\ &= - \sum_j \int_{S^{N-1}} \left(\sum_i \chi_j^i(\omega) \cdot \Phi_i B_i^{-1} \right) v_j \cdot \Psi_j d\omega \\ &= - \sum_j \int_{S^{N-1}} B_j^{-1} K_j^\Phi(\omega) \psi_j(\omega) d\omega. \end{aligned}$$

Hence we have

$$\begin{aligned} \mathcal{D}(\Psi, \Phi) &= - \sum_i \int_{S^{N-1}} \psi_i(\omega) Q^{*-1}(\phi)_i(\omega) B_i^{-1} d\omega \\ &= - \sum_i \left(\Psi_i \cdot \left(\int_{S^{N-1}} v_i K_i^\Phi d\omega \right) B_i^{-1} \right). \end{aligned} \quad (24)$$

The lemma follows, since the first expression recasts as

$$-\sum_i \int_{S^{N-1}} Q^*(K^\Psi)_i(\omega) K_i^\Phi(\omega) B_i^{-1} d\omega = \mathcal{B}_\theta(K^\Phi, K^\Psi),$$

which easily leads to the conclusion by using Corollary 3.

We are thus left with the task of proving (23). However, this is a simple consequence of the linearity of Q^* , which implies that summation over i commutes with the action of this operator. We are thus able to show that Q^* acts on the right hand side of (23) as follows

$$\begin{aligned} Q^*\left(\sum_i B_i \chi^i \cdot \Phi_i B_i^{-1}\right)_j &= \sum_i Q^*(B_i \chi^i)_j \cdot \Phi_i B_i^{-1} \\ &= \sum_i v_i B_i \delta_{ij} \cdot \Phi_i B_i^{-1} = v_j \cdot \Phi_j = \phi_j = Q^*(K^\Phi)_j. \end{aligned}$$

□

From Lemma 1, we can deduce the following claim which will give a precise meaning to the current relation (19). It will play a key role in our rigorous analysis.

COROLLARY 4 *We can define a linear, continuous and invertible mapping $\mathcal{J} : \mathbb{H} \rightarrow \mathbb{H}'$ such that, for any Φ and Ψ in \mathbb{H} one has*

$$\mathcal{D}(\Phi, \Psi) = -(\mathcal{J}(\Phi), \Psi)_\ell = -\sum_i \mathcal{J}(\Phi)_i \Psi_i B_i^{-1}.$$

Proof. For any $\Phi \in \mathbb{H}$, the Riesz theorem defines a unique $\mathcal{J}(\Phi) \in \mathbb{H}'$, such that $\mathcal{D}(\Phi, \Psi) = -(\mathcal{J}(\Phi), \Psi)_\ell$ for any $\Psi \in \mathbb{H}$. The corresponding mapping $\mathcal{J} : \mathbb{H} \rightarrow \mathbb{H}'$ is of course linear and continuous. Conversely, let $J \in \mathbb{H}'$. The Lax-Milgram theorem applies to solve the variational problem

find $\Phi \in \mathbb{H}$ such that, for all $\Psi \in \mathbb{H}$ one has $\mathcal{D}(\Phi, \Psi) = -(J, \Psi)_\ell$.

By Proposition 4, this problem admits a unique solution $\Phi \in \mathbb{H}$ which satisfies, by its definition, $\mathcal{J}(\Phi) = J$. □

This statement will allow us to interpret the current equation (19) in a duality sense by $J = \mathcal{J}(\nabla_x \rho)$. Accordingly, one expects that J lies in $L^2(\mathbb{R}_t^+ \times \mathbb{R}_x^N; \mathbb{H}')$ and $\nabla_x \rho \in L^2(\mathbb{R}_t^+ \times \mathbb{R}_x^N; \mathbb{H})$. It is worth remarking this gain in "regularity", both in the space and energy variables on the density, since this property is not guaranteed in general for ρ^η , for $\eta > 0$. This is an usual fact when dealing with diffusion approximation, see for instance [29], [20]; the noticeable point here is that this effect also applies to the energy variable.

5 Rigorous derivation

This section is devoted to the rigorous study of the asymptotic behaviour as η goes to 0 of the solution f^η of the kinetic equation

$$\begin{cases} \partial_t f_i^\eta + \frac{1}{\eta} v_i \cdot \nabla_x f_i^\eta = \frac{1}{\eta^2} (Q_\theta(f^\eta))_i & \text{in } \mathbb{R}_t^+ \times \mathbb{R}_x^N \times \mathbb{N}_i \times S_\omega^{N-1}, \\ f^\eta(t=0) = F_I^\eta. \end{cases} \quad (25)$$

In order to take into account time and space variables, one needs to define again some functional spaces, based on the previous ones. We set

$$\mathcal{L}^2 = \left\{ f : \mathbb{R}_x^N \times \mathbb{N}_i \times S_\omega^{N-1} \longrightarrow \mathbb{R}, \sum_i \int_{\mathbb{R}^N} \int_{S^{N-1}} f_i^2 B_i^{-1} d\omega dx < \infty \right\}.$$

It is nothing but the L^2 space on $\mathbb{R}^N \times \mathbb{N} \times S^{N-1}$ endowed with the measure $dx \otimes (B_i^{-1} di) \otimes d\omega$, where di stands for the counting measure on \mathbb{N} . Accordingly, we also set

$$\mathcal{E} = \left\{ f : \mathbb{R}_x^N \times \mathbb{N}_i \times S_\omega^{N-1} \longrightarrow \mathbb{R}, \sum_i \int_{\mathbb{R}^N} \int_{S^{N-1}} f_i^2 \frac{\gamma_i}{B_i} d\omega dx < \infty \right\} = L^2(\mathbb{R}^N; \mathbb{E})$$

and

$$\mathcal{F} = \left\{ f : \mathbb{R}_x^N \times \mathbb{N}_i \times S_\omega^{N-1} \longrightarrow \mathbb{R}, \sum_i \int_{\mathbb{R}^N} \int_{S^{N-1}} f_i^2 \frac{1}{\gamma_i B_i} d\omega dx < \infty \right\} = L^2(\mathbb{R}^N; \mathbb{F}).$$

Similarly, for vector-valued macroscopic quantities, independent on the angular variable, we set

$$\mathcal{H} = \left\{ \Phi : \mathbb{R}_x^N \times \mathbb{N}_i \longrightarrow \mathbb{R}^N, \sum_i \int_{\mathbb{R}^N} |\Phi_i|^2 \frac{2\varepsilon_i}{m\gamma_i B_i} dx < \infty \right\} = L^2(\mathbb{R}^N; \mathbb{H})$$

and

$$\mathcal{H}' = \left\{ J : \mathbb{R}_x^N \times \mathbb{N}_i \longrightarrow \mathbb{R}, \sum_i \int_{\mathbb{R}^N} |J_i|^2 \frac{m\gamma_i}{2\varepsilon_i B_i} dx < \infty \right\} = L^2(\mathbb{R}^N; \mathbb{H}').$$

which is the dual of \mathcal{H} when one identifies $L^2(\mathbb{R}^N, \mathcal{L}) = L^2(\mathbb{R}^N \times \mathbb{N}, dx \otimes B_i^{-1} di)$ with its dual, namely

$$\langle J, \Phi \rangle_{\mathcal{H}', \mathcal{H}} = \sum_i \int_{\mathbb{R}^N} \Phi_i \cdot J_i B_i^{-1} dx.$$

We shall not detail the existence theory for the transport equation (25). With some maybe stronger assumptions on the cross-sections, this can be done by means of semi-groups theory. We can also use some monotonicity argument, following R. Petterson [36]. Instead, we shall assume from now on that there exists a function $f^\eta \in C^0(\mathbb{R}^+; \mathcal{L}^2) \cap L^\infty(\mathbb{R}^+; \mathcal{E})$ satisfying the following weak formulation of (25)

$$\begin{aligned} & - \int f^\eta \partial_t \varphi B^{-1} d\mu - \frac{1}{\eta} \int f^\eta v \cdot \nabla_x \varphi B^{-1} d\mu + \left[\int f^\eta \varphi B^{-1} d\nu \right]_0^T \\ & = \frac{1}{\eta^2} \int Q_\theta(f^\eta) \varphi B^{-1} d\mu. \end{aligned} \quad (26)$$

Here, $d\mu$ indicates integration over $(0, T) \times \mathbb{R}^N \times \mathbb{N} \times S^{N-1}$ with the measure $dt \otimes dx \otimes di \otimes d\omega$ while $d\nu$ has the same meaning on $\mathbb{R}^N \times \mathbb{N} \times S^{N-1}$ with the measure $dx \otimes di \otimes d\omega$. Relation (26) holds for any φ in an appropriate space of admissible test functions \mathfrak{D} . In particular, it makes sense for $\varphi \in L_{loc}^1(\mathbb{R}^+; \mathcal{E})$ such that $\partial_t \varphi$ and $\nabla_x \cdot (v\varphi)$ belong to $L_{loc}^1(\mathbb{R}^+; \mathcal{L}^2)$. It is worth remarking that a sequence defined by a finite number of non-zero functions $\varphi_i(t, x, \omega)$ lying in $C_0^1([0, T] \times \mathbb{R}^N; L^\infty(S^{N-1}))$ is admissible.

REMARK 8 *If one assumes that $0 < \gamma_i \leq C < +\infty$, we obtain the inclusions $\mathbb{F} \subset \mathbb{L} \subset \mathbb{E}$, and therefore Q_θ can be viewed as a bounded operator on \mathcal{L}^2 , with values in \mathcal{L}^2 , and existence-uniqueness is easy to be established. Of course, the problem for $\eta > 0$ fixed and most of our convergence analysis become easier if one deals with a finite number of energy groups.*

Then, we can now state our main result.

THEOREM 1 *Suppose (H) and let F_I^η be bounded in \mathcal{L}^2 . Then, $\rho^\eta = \int_{S^{N-1}} f^\eta d\omega$ converges weakly-* in $L^\infty(0, T; L^2(\mathbb{R}^N \times \mathbb{N}; B^{-1} di \otimes dx))$ (and in $C^0([0, T], L^2(\mathbb{R}^N \times \mathbb{N}; B^{-1} di \otimes dx) - \text{weak})$) to ρ and $J^\eta = \int_{S^{N-1}} \sqrt{2\varepsilon i/m\omega} f^\eta d\omega$ converges weakly-* in $L^2(0, T; \mathcal{H}')$ to J (see (27) below). These limits satisfy*

$$\begin{cases} \partial_t \rho + \operatorname{div}_x J = 0, \\ \nabla_x \rho \in L^2(0, T; \mathcal{H}), \end{cases} \quad \text{and} \quad \mathcal{J}(\nabla_x \rho) = J.$$

The proof naturally falls into four steps.

Step 1: A priori estimates and weak convergences

The main estimates on f^η are obtained by formally multiplying equation (25) by f^η/B and integrating. It yields

$$\|f^\eta(t)\|_{\mathcal{L}^2}^2 + \frac{2}{\eta^2} \int_0^t \int_{\mathbb{R}^N} \mathcal{B}_\theta(f^\eta, f^\eta) dx ds = \|F_I^\eta\|_{\mathcal{L}^2}^2.$$

Therefore, the coercivity of \mathcal{B}_θ allows us to estimate $\|f^\eta\|_{\mathcal{L}^2}$ and $\frac{1}{\eta} N(f^\eta - \rho^\eta) = N(g^\eta)$ and thus leads to the following statement.

LEMMA 2 *Suppose that (H) holds and let F_I^η be bounded in \mathcal{L}^2 . Then,*

- i) f^η is bounded in $L^\infty(\mathbb{R}_t^+; \mathcal{L}^2)$, with $\|f^\eta(t)\|_{\mathcal{L}^2}^2 \leq \|F_I^\eta\|_{\mathcal{L}^2}^2 \leq C$.
- ii) $g^\eta = (f^\eta - \rho^\eta)/\eta$ is bounded in $L^2(\mathbb{R}_t^+; \mathcal{E})$,
- iii) $\rho_i^\eta(t, x) = \int_{S^{N-1}} f_i^\eta(t, x, \omega) d\omega$ is bounded in $L^\infty(\mathbb{R}_t^+; L^2(\mathbb{R}^N \times \mathbb{N}, dx \otimes B_i^{-1} di))$,
- iv) $J_i^\eta(t, x) = 1/\eta \int_{S^{N-1}} v_i f_i^\eta(t, x, \omega) d\omega = \int_{S^{N-1}} (2\varepsilon i)/m \omega g_i^\eta(t, x, \omega) d\omega$ is bounded in $L^\infty(\mathbb{R}_t^+; \mathcal{H}')$.

Proof. It remains to establish the bounds on the macroscopic quantities. Clearly, one has

$$\sum_i \int_{\mathbb{R}^N} |\rho_i^\eta|^2 B_i^{-1} dx = \sum_i \int_{\mathbb{R}^N} \left| \int_{S^{N-1}} f_i^\eta d\omega \right|^2 B_i^{-1} dx \leq \|f^\eta\|_{\mathcal{L}^2}^2.$$

Next, the current satisfies

$$\begin{aligned} \sum_i \int_{\mathbb{R}^+} \int_{\mathbb{R}^N} |J_i^\eta|^2 \frac{m\gamma_i}{2\varepsilon i B_i} dx dt &= \sum_i \int_{\mathbb{R}^+} \int_{\mathbb{R}^N} \left| \int_{S^{N-1}} \sqrt{\frac{2\varepsilon i}{m}} \omega g_i^\eta d\omega \right|^2 \frac{m\gamma_i}{2\varepsilon i B_i} dx dt \\ &\leq \sum_i \int_{\mathbb{R}^+} \int_{\mathbb{R}^N} \int_{S^{N-1}} |g_i^\eta|^2 \frac{\gamma_i}{B_i} d\omega dx dt \\ &\leq \int_{\mathbb{R}^+} \int_{\mathbb{R}^N} N(g^\eta)^2 dx dt \end{aligned}$$

and the boundedness of J^η is a consequence of ii). \square

Possibly at the cost of extracting subsequences, we can assume that

$$\begin{cases} f^\eta \rightharpoonup_* f & \text{weakly } * \text{ in } L^\infty(\mathbb{R}_t^+; \mathcal{L}^2), \\ g^\eta \rightharpoonup_* g & \text{weakly } * \text{ in } L^2(\mathbb{R}_t^+; \mathcal{E}), \\ \rho^\eta \rightharpoonup_* \rho & \text{weakly } * \text{ in } L^\infty(\mathbb{R}_t^+; L^2(\mathbb{R}^N \times \mathbb{N}, dx \otimes B_i^{-1} di)), \\ J^\eta \rightharpoonup_* J & \text{weakly } * \text{ in } L^2(\mathbb{R}_t^+; \mathcal{H}'). \end{cases} \quad (27)$$

This means, respectively

$$\left\{ \begin{array}{l} \lim_{\eta \rightarrow 0} \int f^\eta \varphi B_i^{-1} d\mu = \int f \varphi B^{-1} d\mu \\ \quad \text{where } \int_{\mathbb{R}^+} \left(\int_{\mathbb{R}^N \times \mathbb{N} \times S^{N-1}} \varphi_i(t, x, \omega)^2 B_i^{-1} d\omega di dx \right)^{1/2} dt < \infty, \\ \lim_{\eta \rightarrow 0} \int g^\eta \psi B_i^{-1} d\mu = \int g \psi B^{-1} d\mu \\ \quad \text{where } \int \psi_i(t, x, \omega)^2 (\gamma_i B_i)^{-1} d\mu < \infty, \\ \lim_{\eta \rightarrow 0} \int_{\mathbb{R}^+ \times \mathbb{R}^N \times \mathbb{N}} \rho^\eta \kappa B_i^{-1} di dx dt = \int_{\mathbb{R}^+ \times \mathbb{R}^N \times \mathbb{N}} \rho \kappa B^{-1} di dx dt \\ \quad \text{where } \int_{\mathbb{R}^+} \left(\int_{\mathbb{R}^+ \times \mathbb{R}^N \times \mathbb{N}} \kappa_i(t, x)^2 B_i^{-1} di dx \right)^{1/2} dt < \infty, \\ \lim_{\eta \rightarrow 0} \int_{\mathbb{R}^+ \times \mathbb{R}^N \times \mathbb{N}} J^\eta \cdot \Phi B^{-1} di dx dt = \int_{\mathbb{R}^N \times \mathbb{N}} J \cdot \Phi B^{-1} di dx dt \\ \quad \text{where } \int_{\mathbb{R}^+ \times \mathbb{R}^N \times \mathbb{N}} |\Phi_i(t, x)|^2 \frac{2\varepsilon i}{m\gamma_i B_i} di dx dt < \infty. \end{array} \right.$$

Choosing, with the above properties, $\varphi_i(t, x, \omega) = \kappa_i(t, x)$ and $\psi_i(t, x, \omega) = (2\varepsilon i/m)^{1/2} \omega \cdot \Phi_i(t, x)$, we realize that

$$\rho = \int_{S^{N-1}} f d\omega, \quad J = \int_{S^{N-1}} \sqrt{\frac{2\varepsilon i}{m}} \omega g d\omega$$

holds. In fact, we obviously have $f = \rho$ by taking the limit in the distributional sense in $f^\eta = \rho^\eta + \eta g^\eta$.

Step 2: Continuity equation

We wish to establish the following claim.

LEMMA 3 *For any i the continuity relation*

$$\partial_t \rho_i + \operatorname{div}_x J_i = 0$$

holds in $\mathcal{D}'((0, T) \times \mathbb{R}^N)$.

Proof. We use in (26) the test function $\kappa_i B_i \zeta(t, x)$ with $\kappa_i \in \ell^\infty$ (precisely $\kappa_i = \delta_{ij}$), and $\zeta \in C_0^\infty((0, T) \times \mathbb{R}^N)$; then we take the limit $\eta \rightarrow 0$. \square

REMARK 9 Under suitable hypotheses, one could also rigorously derive the inelastic term (22). Actually, if $\sigma_{ij}(\omega, \omega')$ is such that Q_θ^{inel} is bounded in \mathbb{L} , a-priori estimate can still be derived by means of an application of Gronwall's lemma when $Q_\theta = Q_\theta^{el} + \eta^2 Q_\theta^{inel}$.

Step 3: Current equation

According to our discussion in the previous section, the expected current equation $J = -\sum_j D_{ij} \nabla_x \rho_j$ has to be understood in the dual sense $\mathcal{J}(\nabla_x \rho) = J$ which means that

$$\mathcal{D}(\nabla_x \rho, \Phi) = -\langle J, \Phi \rangle \quad (28)$$

holds for any $\Phi \in L^2(\mathbb{R}^+, \mathcal{H})$. Of course, the notation now takes into account the time and space variables. Precisely, the right hand side reads

$$\int J \cdot \Phi B^{-1} di dx dt = \int gv \cdot \Phi B^{-1} d\mu.$$

Since we can associate to $\Phi \in L^2(\mathbb{R}^+, \mathcal{H})$ a unique $K^\Phi \in L^2(\mathbb{R}^+, \mathcal{E})$ (with null average) such that $Q^*(K^\Phi) = v \cdot \Phi$, we get

$$(J, \Phi) = \int gQ^*(K^\Phi) B^{-1} d\mu.$$

On the other hand, the left hand side in (28) is

$$-\int \nabla_x \rho \cdot vK^\Phi B^{-1} d\mu = -\int_{\mathbb{R} \times \mathbb{N} \times \mathbb{R}^N} \nabla_x \rho \left(\int_{S^{N-1}} vK^\Phi d\omega \right) B_i^{-1} di dx dt$$

by using (23). Then, (28) reduces to

$$\int gQ^*(K^\Phi) B^{-1} d\mu = \int_{\mathbb{R} \times \mathbb{N} \times \mathbb{R}^N} \nabla_x \rho \left(\int_{S^{N-1}} vK^\Phi d\omega \right) B^{-1} di dx dt \quad (29)$$

In order to justify equality (28), it thus would be tempting to use $\varphi = K^\Phi$ as test function in (26). However, difficulties arise when we ask for such a function to belong to the admissible set \mathcal{D} . We note that, for $\Phi \in L^2(0, T; \mathcal{H})$, we naturally have $K^\Phi \in L^2(0, T; \mathcal{E})$ and $\int_{S^{N-1}} vK^\Phi d\omega \in L^2(0, T; \mathcal{H}')$. However we recall that it is required that $\nabla_x \cdot (v\varphi) \in L^2(0, T; \mathcal{L}^2)$ for φ to be an admissible test function. Space regularity is not a real difficulty, but it is not clear how it can be guaranteed that vK^Φ belongs to $L^2(0, T; \mathcal{L}^2)$. Except in some very particular cases (for instance if $2\epsilon i \leq C\gamma_i$ which implies that \mathcal{H}' embeds to \mathcal{L} or in some isotropic case as in [19]), since Q_θ^{-1} mixes all the energy levels, it seems that a truncation of Φ on the high levels does not give such a control and it is not clear at all that the set $\{\Phi \in L^2(0, T; \mathcal{H}), \nabla_x \cdot vK^\Phi \in L^2(0, T; \mathcal{L}^2)\}$ is not empty in the general case. This difficulty leads to some technical restrictions on the cross-sections in [19].

On the other hand, if we are able to prove that $\nabla_x \rho \in L^2(0, T; \mathcal{H})$, then, the relation (29) makes sense provided $\Phi \in L^2(0, T; \mathcal{H})$ and does not require further property on Φ . This motivates our strategy of proof: First, we establish an approximate current equation, from which we will be able to deduce that $\nabla_x \rho \in L^2(0, T; \mathcal{H})$; and then we derive the current equation (29). We are thus led to the main statement of the step.

PROPOSITION 5 *We have $\nabla_x \rho \in L^2(0, T; \mathcal{H})$, and the limit J of J^η satisfies (29).*

Proof. Let Φ be a test function in $L^2(0, T; \mathcal{H})$ compactly supported with respect to time in $(0, T)$. Moreover, one assumes that $\partial_t \Phi \in L^2(0, T; \mathcal{L})$ and $\nabla_x \Phi \in L^2(0, T; \mathcal{H})$. This can be obtained by regularizing in time and space and eventually truncating in energy a function in $L^2(0, T; \mathcal{H})$. Then, $Q_\theta^{*-1}(v \cdot \Phi) = K^\Phi \in L^2(0, T; \mathcal{E})$ (recall that K^Φ depends on ω , though Φ does not). We introduce the function $\mu^{(n)}$ defined on \mathbb{N} by

$$\mu_i^{(n)} = \begin{cases} 1 & \text{if } i \leq n, \\ 0 & \text{if } i > n. \end{cases}$$

The parameter n will help us in approximating (29). Then, we consider the admissible test function $\varphi_i(t, x, \omega) = \mu_i^{(n)} K_i^\Phi(t, x, \omega) \in L^2(0, T; \mathcal{E})$. We obtain from (26)

$$- \int f^\eta v \cdot \nabla_x (\mu^{(n)} K^\Phi) B^{-1} d\mu - \eta \int f^\eta \partial_t (\mu^{(n)} K^\Phi) B^{-1} d\mu = \frac{1}{\eta} \int Q_\theta(f^\eta) \mu^{(n)} K^\Phi B^{-1} d\mu. \quad (30)$$

The right hand side gives

$$\int Q_\theta(g^\eta) \mu^{(n)} K^\Phi B^{-1} d\mu = \int g^\eta Q_\theta^*(\mu^{(n)} K^\Phi) B^{-1} d\mu,$$

while the left hand side is rewritten

$$- \int \rho^\eta \mu^{(n)} v \cdot \nabla_x K^\Phi B^{-1} d\mu - \eta \left(\int f^\eta \partial_t (\mu^{(n)} K^\Phi) B^{-1} d\mu + \int g^\eta \mu^{(n)} v \cdot \nabla_x K^\Phi B^{-1} d\mu \right).$$

Since all the sums are actually finite, there is no trouble in applying convergences (27), n being fixed. The left hand side in (30) tends, as η goes to 0, towards

$$- \int \rho \nabla_x \cdot (v_j \mu^{(n)} v K^\Phi) B^{-1} d\mu = - \int_{\mathbb{R}^+ \times \mathbb{R}^N \times \mathbb{N}} (\mu^{(n)} \rho) \nabla_x \cdot \left(\int_{S^{N-1}} v K^\Phi d\omega \right) B^{-1} di dx dt.$$

Moreover, the right hand side in (30) becomes

$$\int g^\eta Q_\theta^*(\mu^{(n)} K^\Phi) B^{-1} d\mu \longrightarrow \int g Q_\theta^*(\mu^{(n)} K^\Phi) B^{-1} d\mu.$$

Thus, we are led to the equality

$$- \int_{\mathbb{R}^+ \times \mathbb{R}^N \times \mathbb{N}} (\mu^{(n)} \rho) \nabla_x \cdot \left(\int_{S^{N-1}} v K^\Phi d\omega \right) B^{-1} di dx dt = \int g Q_\theta^*(\mu^{(n)} K^\Phi) B^{-1} d\mu, \quad (31)$$

which appears as an approximate form of (28). We wish to conclude by letting n go to ∞ . Let us introduce the linear mapping $J^{(n)}$ defined on the set

$$\left\{ \Phi \in L^2(0, T; \mathcal{H}), \nabla_x \cdot \left(\int_{S^{N-1}} v K^\Phi d\omega \right) \in L^2(0, T; \mathcal{H}') \right\}$$

by

$$J^{(n)}(\Phi) = - \int_{\mathbb{R}^+ \times \mathbb{R}^N \times \mathbb{N}} (\mu^{(n)} \rho) \nabla_x \cdot \left(\int_{S^{N-1}} v K^\Phi d\omega \right) B^{-1} di dx dt,$$

which corresponds to a weak definition of $-\mathcal{D}(\mu^{(n)} \nabla_x \rho, \Phi)$. Note that this set is obviously dense in $L^2(0, T; \mathcal{H})$ (it is only concerned with space regularization since $\int_{S^{N-1}} v K^\Phi d\omega$ naturally lies in $L^2(0, T; \mathcal{H}')$). Furthermore, (31) says that one actually has

$$J^{(n)}(\Phi) = \int g Q_\delta^*(\mu^{(n)} K^\Phi) B^{-1} d\mu.$$

One deduces that

$$|J^{(n)}(\Phi)| \leq C \|g\|_{L^2(0, T; \mathcal{E})} \|\Phi\|_{L^2(0, T; \mathcal{H})}$$

and $J^{(n)}$ is a bounded sequence of continuous linear forms defined on the whole space $L^2(0, T; \mathcal{H})$. According to Corollary 4, we can associate a sequence $\Theta^{(n)}$ satisfying

$$\|\Theta^{(n)}\|_{L^2(0, T; \mathcal{H})} \leq C \|g\|_{L^2(0, T; \mathcal{E})},$$

and

$$J^{(n)}(\Phi) = -\mathcal{D}(\Theta^{(n)}, \Phi) = \int_{\mathbb{R}^+ \times \mathbb{R}^N \times \mathbb{N}} \Theta_i^{(n)}(t, x) \left(\int_{S^{N-1}} v_i K_i^\Phi(t, x, \omega) d\omega \right) B_i^{-1} di dx dt,$$

for any $\Phi \in L^2(0, T; \mathcal{H})$ (where we used (24)). Then, coming back to (31), $\Theta^{(n)}$ is a bounded sequence in $L^2(0, T; \mathcal{H})$ which coincides with $\mu^{(n)} \nabla_x \rho$ as a linear form on the subset $\{\int_{S^{N-1}} v K^\Phi d\omega, \Phi \in L^2(0, T; \mathcal{H})\} \subset L^2(0, T; \mathcal{H}')$. Hence, we will conclude that the limit of $\Theta^{(n)}$ defines $\nabla_x \rho$ as element of $L^2(0, T; \mathcal{H})$ if we are able to prove the following claim.

LEMMA 4 *The set $\mathbb{K} = \{\int_{S^{N-1}} v K^\Phi d\omega, \Phi \in \mathbb{H}\}$ is dense in \mathbb{H}' .*

Lemma 4 yields $\mu^{(n)} \nabla_x \rho = \Theta^{(n)}$ in $L^2(0, T; \mathcal{H})$, and therefore $\mu^{(n)} \nabla_x \rho$ is bounded in this space, uniformly with respect to n . Since the sequence converges towards $\nabla_x \rho$ as $n \rightarrow \infty$ in a distributional sense, we deduce that $\mu^{(n)} \nabla_x \rho$ converges weakly towards $\nabla_x \rho$ in $L^2(0, T; \mathcal{H})$.

We end the proof by taking the limit $n \rightarrow \infty$ in the equality (31); we finally get

$$-\mathcal{D}(\nabla_x \rho, \Phi) = \int g v \cdot \Phi B^{-1} d\mu = \int_{\mathbb{R}^+ \times \mathbb{R}^N \times \mathbb{N}} J \cdot \Phi B^{-1} di dx dt.$$

Now, it remains to justify Lemma 4. \square

Proof of Lemma 4. It is equivalent to prove that the orthogonal set of \mathbb{K} is reduced to 0 in \mathbb{H} . Let $\Theta \in \mathbb{H}$ satisfy

$$\left(\Theta, \int_{S^{N-1}} v K^\Phi d\omega \right)_L = 0, \quad \forall \Phi \in \mathbb{H}.$$

Then, by (24), this reads $\mathcal{D}(\Theta, \Phi) = 0$ for all $\Phi \in \mathbb{H}$, which yields $\Theta = 0$ thanks to the coercivity of the bilinear form \mathcal{D} . \square

Step 4: Compactness in time.

We would like to recover as initial data ρ_I for the limit problem a function depending on the behaviour of the sequence of data F_I^η for the kinetic equation. Of course this relies on a compactness in time property, at least for some weak topology. On the other hand, it can be shown a uniqueness result for the limit equation in the class of continuous functions with value in $L^2(\mathbb{R}^N \times \mathbb{N}; B^{-1} di \otimes dx)$ and having the gradient in $L^2(0, T; \mathcal{H})$. In turn, of course, the whole sequence ρ^η will converge to this ρ .

LEMMA 5 *The sequence $(\rho^\eta)_{\eta>0}$ is sequentially compact in $C^0([0, T]; L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1} di \otimes dx)$ – weak). In particular, there exists a sequence $(\rho^{\eta_n})_{n \in \mathbb{N}}$ such that for any $\phi \in L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1} di \otimes dx)$*

$$\int_{\mathbb{R}^N} \rho^{\eta_n} \phi B^{-1} di dx \longrightarrow \int_{\mathbb{R}^N} \rho \phi B^{-1} di dx$$

as $n \rightarrow \infty$ in $C^0([0, T])$.

Proof. First, let $\psi \in L^2(\mathbb{R}^N \times \mathbb{N}, (1 + i/\gamma_i) B_i^{-1} di \otimes dx)$ with $\nabla_x \psi \in \mathcal{H}$. Looking at the continuity equation, one gets

$$\begin{aligned} \int_{\mathbb{R}^N} \rho^\eta(t) \psi B^{-1} di dx - \int_{\mathbb{R}^N} \rho^\eta(s) \psi B^{-1} di dx &= \int_0^t (J^\eta, \nabla_x \psi)_{\mathcal{H}', \mathcal{H}} d\sigma \\ &\leq C \|J^\eta\|_{L^2(0, T; \mathcal{H}')} \sqrt{|t-s|} \|\nabla_x \psi\|_{\mathcal{H}}. \end{aligned}$$

The bound iv) in Proposition 2 combined to the Arzela–Ascoli theorem allows us to deduce that $(\int \rho^\eta(t) \psi B^{-1} di dx)_{\eta>0}$ lies in a compact set in $C^0([0, T])$. By considering finite series and space regularization, one sees that the set of the ψ 's used above is dense into $L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1} di \otimes dx)$. Then, let $\phi \in L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1} di \otimes dx)$. We deduce that, for any $\varepsilon > 0$,

$$\left(\int_{\mathbb{R}^N} \rho^\eta(t) \phi B^{-1} di dx \right)_{\eta>0} \subset B(0, \varepsilon) + \text{Compact Set} \quad \text{in } C^0([0, T]).$$

Hence, $(\int \rho^\eta(t) \phi B^{-1} di dx)_{\eta>0}$ also lies in a compact set in $C^0([0, T])$. We conclude by using the separability of $L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1} di \otimes dx)$ and a Cantor argument. \square

Lemma 5 says that we recover as initial data for the limit equation the limit, in the weak $L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1} di \otimes dx)$ sense, of $\rho_I^\eta = \int_{S^{N-1}} F_I^\eta d\omega$. Moreover, classical reasoning gives the continuity in time for the limit problem, see for instance [16].

LEMMA 6 *The limit ρ is a continuous function on $[0, T]$ with values in $L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1} di \otimes dx)$; and it satisfies*

$$\frac{d}{dt} \|\rho\|_{L^2}^2 = -2 \int_{\mathbb{R}^N} \mathcal{D}(\nabla_x \rho, \nabla_x \rho) dx \quad (32)$$

in $\mathcal{D}'([0, T])$.

Proof. The point relies on the following facts:

$$\begin{cases} \rho \in L^\infty(\mathbb{R}^+; L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1} di \otimes dx)), \\ \rho \in C^0([0, T]; L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1} di \otimes dx) - weak), \\ \nabla_x \rho \in L^2(\mathbb{R}^+; \mathcal{H}). \end{cases}$$

In turn, the equation (21) implies that $\partial_t \rho$ reads as the space derivative of an element of $L^2(\mathbb{R}^+; \mathcal{H}')$. This legitimates the product with ρ . Indeed, by regularization (in time) and truncation (in energy), we can construct a sequence $\rho^{(n)}$ which lies in $C^\infty([0, T]; \mathcal{H} \cap L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1} di \otimes dx))$, with $\partial_t \rho^{(n)} \in C^\infty([0, T]; \mathcal{H}' \cap L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1} di \otimes dx))$ and satisfying

$$\begin{cases} \rho^{(n)} \rightarrow \rho & \text{in } L^2(0, T; L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1} di \otimes dx)), \\ \partial_t \rho^{(n)} \rightarrow \partial_t \rho & \text{in } L^2(0, T; \nabla_x \cdot (\mathcal{H}')) \end{cases}$$

as n goes to ∞ . When dealing with regular functions, one has clearly

$$\frac{d}{dt} \|\rho^{(n)}\|_{L^2}^2 = 2(\partial_t \rho^{(n)}, \rho^{(n)})_{L^2} = 2\langle \partial_t \rho^{(n)}, \rho^{(n)} \rangle$$

where the brackets stands for the duality product between $\{\rho \text{ such that } \nabla_x \rho \in \mathcal{H}\}$ and $\{\sum_{|\alpha|=1} \partial_x^\alpha J, J \in \mathcal{H}'\}$. Passing to the limit $n \rightarrow \infty$ justifies that

$$\frac{d}{dt} \|\rho\|_{L^2} = 2\langle \partial_t \rho, \rho \rangle$$

holds in $\mathcal{D}'(]0, T[)$, which gives (32). Therefore, one deduces that $\frac{d}{dt} \|\rho\|_{L^2} \in L^1(0, T)$ and

$$\|\rho(t)\|_{L^2}^2 = \|\rho_I\|_{L^2}^2 + \int_0^t 2\langle \partial_t \rho, \rho \rangle ds$$

defines a continuous function on $[0, T]$. Furthermore,

$$\|\rho(t) - \rho(t_0)\|_{L^2}^2 = \|\rho(t)\|_{L^2}^2 + \|\rho(t_0)\|_{L^2}^2 - 2(\rho(t), \rho(t_0))_{L^2}$$

tends to 0 as t goes to t_0 since $\rho \in C^0([0, T], L^2 - weak)$. \square

In turn, one deduces the following uniqueness statement which proves that the whole sequence ρ^n converges.

COROLLARY 5 *There exists a unique solution ρ of (21) with $\rho \in L^\infty(\mathbb{R}^+; L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1} di \otimes dx))$ and $\nabla_x \rho \in L^2(\mathbb{R}^+; \mathcal{H})$.*

Proof. The previous Lemma guarantees that ρ is continuous with values in $L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1} di \otimes dx)$. By linearity, it suffices to consider the solution ρ corresponding to data $\rho_I = 0$. Then, (32) combined to the positivity of \mathcal{D} implies that $\|\rho(t)\|_{L^2} = 0$. \square

As a concluding remark, let us notice that we can improve the convergence of ρ^n to ρ . Indeed, using $\omega \delta_{ij}$ as test function in (26), we obtain that $\nabla_x \rho_i$ reads as a bounded term

in $L^2((0, T) \times \mathbb{R}^N)$ plus $\eta \times$ (first derivatives of bounded terms in $L^2((0, T) \times \mathbb{R}^N)$), hence it is compact in $H^{-1}((0, T) \times B(0, R))$ for any $0 < T, R < \infty$. Combining this information to the continuity equation in Lemma 3, we can apply the Div-Curl argument of L. Tartar [39], as in [34], [29], [20], [28] and we deduce that for any $i \in \mathbb{N}$, ρ_i^η lies in a compact set of $L^2_{loc}((0, T) \times \mathbb{R}^N)$. If further the B_i 's tend to 0, one easily concludes that ρ^η converges to ρ strongly in $L^2((0, T) \times B(0, R) \times \mathbb{N})$, for any $0 < T, R < \infty$.

A Properties of the collision operators

A.1 Proof of Proposition 1

We write $Q_0^{el}(f)_i = K(f)_i - \Sigma_i f_i$. Of course, one has $\|\Sigma f\|_{\mathbb{F}} = \|f\|_{\mathbb{E}}$. Next, using (h1), we get

$$\begin{aligned}
& \sum_i \int_{S^{N-1}} |K(f)_i|^2 \frac{1}{\Sigma_i B_i} d\omega = \\
& = \sum_i \int_{S^{N-1}} \left| \int_{S^{N-1}} \Gamma_i(\omega', \omega) f_i(\omega') d\omega' \right|^2 \frac{1}{\Sigma_i B_i} d\omega \\
& \leq \sum_i \int_{S^{N-1}} \left\{ \left(\int_{S^{N-1}} \Gamma_i(\omega', \omega) d\omega \right) |f_i(\omega')|^2 d\omega' \int_{S^{N-1}} \Gamma_i(\omega, \omega') d\omega' \frac{1}{\Sigma_i B_i} \right\} d\omega \\
& \leq \sum_i \int_{S^{N-1}} \Sigma_i(\omega') |f_i(\omega')|^2 B_i^{-1} d\omega' = \|f\|_{\mathbb{E}}^2.
\end{aligned} \tag{33}$$

It follows that $Q_0^{el} \in \mathcal{L}(\mathbb{E}, \mathbb{F})$, with $\|Q_0^{el}(f)\|_{\mathbb{F}} \leq 2\|f\|_{\mathbb{E}}$. According to Hypothesis (h1), we easily get (i)

$$\int_{S^{N-1}} Q_0^{el}(f)_i d\omega = \int_{S^{N-1}} f_i(\omega) \left(\int_{S^{N-1}} (\Gamma_i(\omega, \omega') - \Gamma_i(\omega', \omega)) d\omega' \right) d\omega = 0.$$

Now, \mathcal{B}_0 is clearly bilinear and continuous on $\mathbb{E} \times \mathbb{E}$ and we compute

$$\begin{aligned}
\mathcal{B}_0(f, f) &= -\sum_i \int_{S^{N-1}} \int_{S^{N-1}} \Gamma_i(\omega', \omega) [f_i(\omega') - f_i(\omega)] f_i(\omega) B_i^{-1} d\omega' d\omega \\
&= -\sum_i \int_{S^{N-1}} \int_{S^{N-1}} \Gamma_i(\omega', \omega) f_i(\omega) f_i(\omega') B_i^{-1} d\omega' d\omega \\
&\quad + \frac{1}{2} \sum_i \int_{S^{N-1}} \int_{S^{N-1}} \Gamma_i(\omega', \omega) |f_i(\omega)|^2 d\omega' d\omega \\
&\quad + \frac{1}{2} \sum_i \int_{S^{N-1}} \int_{S^{N-1}} \Gamma_i(\omega, \omega') |f_i(\omega')|^2 d\omega' d\omega \\
&= 1/2 \sum_i \int_{S^{N-1}} \int_{S^{N-1}} \Gamma_i(\omega', \omega) \left(|f_i(\omega)|^2 + |f_i(\omega')|^2 \right. \\
&\quad \left. - 2f_i(\omega)f_i(\omega') \right) B_i^{-1} d\omega' d\omega \\
&= 1/2 \sum_i \int_{S^{N-1}} \int_{S^{N-1}} \Gamma_i(\omega', \omega) |f_i(\omega) - f_i(\omega')|^2 B_i^{-1} d\omega' d\omega.
\end{aligned}$$

This obviously leads to the characterization of the kernel of Q_0^{el} in (iii).

Moreover, we have

$$\begin{aligned}
&\sum_i \int_{S^{N-1}} |Q_0^{el}(f)_i|^2 \frac{1}{\Sigma_i B_i} d\omega \\
&\leq \sum_i \int_{S^{N-1}} \int_{S^{N-1}} \Gamma_i(\omega', \omega) |f_i(\omega) - f_i(\omega')|^2 \frac{\Sigma_i}{\Sigma_i B_i} d\omega' d\omega \leq 2\mathcal{B}_0(f, f),
\end{aligned}$$

which implies the last inequality in assertion (ii). \square

A.2 Proof of Corollary 1

Set $f = \langle f \rangle - r$. Since r has null average, Assumption (h2) yields

$$\begin{aligned}
\mathcal{B}_0(f, f) &= 1/2 \sum_i \int_{S^{N-1}} \int_{S^{N-1}} \Gamma_i(\omega', \omega) |f_i(\omega') - f_i(\omega)|^2 B_i^{-1} d\omega' d\omega \\
&\geq 1/2 \sum_i \int_{S^{N-1}} \int_{S^{N-1}} |f_i(\omega') - f_i(\omega)|^2 \gamma_i B_i^{-1} d\omega' d\omega \\
&\geq 1/2 \sum_i \int_{S^{N-1}} \int_{S^{N-1}} |r_i(\omega') - r_i(\omega)|^2 \gamma_i B_i^{-1} d\omega' d\omega \\
&\geq 1/2 \sum_i \int_{S^{N-1}} \int_{S^{N-1}} (r_i^2(\omega') + r_i^2(\omega) - 2r_i(\omega)r_i(\omega')) \gamma_i B_i^{-1} d\omega' d\omega \\
&\geq \sum_i \int_{S^{N-1}} r_i^2(\omega) \gamma_i B_i^{-1} d\omega = N^2(r).
\end{aligned}$$

\square

A.3 Proof of Proposition 2

First, let us estimate

$$\begin{aligned}
\|Q_1^{el}(f)\|_{\mathbb{F}}^2 &= \sum_i \int_{S^{N-1}} \left| \sum_j \int_{S^{N-1}} \sigma_{ij}(\omega, \omega') (f_j(\omega') - f_j(\omega)) d\omega' \right|^2 (\Sigma_i(\omega) B_i)^{-1} d\omega \\
&\leq \sum_i \int_{S^{N-1}} \left(\sum_j \int_{S^{N-1}} \sigma_{ij}(\omega, \omega') B_j d\omega' \right. \\
&\quad \left. \times \sum_j \int_{S^{N-1}} \sigma_{ij}(\omega, \omega') |f_j(\omega') - f_j(\omega)|^2 B_j^{-1} d\omega' \right) (\Sigma_i B_i)^{-1} d\omega \\
&\leq M_2 \sum_j \int_{S^{N-1}} \int_{S^{N-1}} \left(\sum_i \sigma_{ij}(\omega, \omega') \right) |f_j(\omega') - f_j(\omega)|^2 B_j^{-1} d\omega' d\omega \\
&\leq M_2 \sum_j \int_{S^{N-1}} \int_{S^{N-1}} \Gamma_j(\omega, \omega') |f_j(\omega') - f_j(\omega)|^2 B_j^{-1} d\omega' d\omega \\
&\leq 2M_2 \mathcal{B}_0(f, f) \leq 2M_2 \|Q_0^{el}(f)\|_{\mathbb{F}} \|f\|_{\mathbb{E}} \leq 4M_2 \|f\|_{\mathbb{E}}^2
\end{aligned} \tag{34}$$

where we used the Cauchy-Schwarz inequality and the results in Proposition 1. This proves that $Q_1^{el} \in \mathcal{L}(\mathbb{E}, \mathbb{F})$.

In view of Remark 2, we can integrate Q_1^{el} with respect to ω and we get

$$\begin{aligned}
\int_{S^{N-1}} Q_1^{el}(f)_i d\omega &= \sum_j \int_{S^{N-1}} f_j(\omega') \left(\int_{S^{N-1}} \sigma_{ij}(\omega, \omega') d\omega \right) d\omega' \\
&\quad - \sum_j \int_{S^{N-1}} f_j(\omega) \left(\int_{S^{N-1}} \sigma_{ij}(\omega, \omega') d\omega' \right) d\omega \\
&= \sum_j \int_{S^{N-1}} f_j(\omega) \left(\int_{S^{N-1}} (\sigma_{ij}(\omega', \omega) - \sigma_{ij}(\omega, \omega')) d\omega' \right) d\omega \\
&= 0,
\end{aligned}$$

by using the symmetry assumption (h1').

Then, \mathcal{B}_1 is obviously a bilinear continuous form on \mathbb{E} , and a straightforward computation yields

$$\begin{aligned}
\mathcal{B}_1(f, g) &= - \sum_{i,j} \int_{S^{N-1}} \int_{S^{N-1}} \sigma_{ij}(\omega, \omega') (f_j(\omega') - f_j(\omega)) g_i(\omega) B_i^{-1} d\omega' d\omega \\
&= \sum_{i,j} \int_{S^{N-1}} \int_{S^{N-1}} \sigma_{ij}(\omega', \omega) (f_j(\omega') - f_j(\omega)) g_i(\omega') B_i^{-1} d\omega d\omega' \\
&= 1/2 \sum_{i,j} \int_{S^{N-1}} \int_{S^{N-1}} (f_j(\omega') - f_j(\omega)) \\
&\quad (\sigma_{ij}(\omega', \omega) g_i(\omega') - \sigma_{ij}(\omega, \omega') g_i(\omega)) B_i^{-1} d\omega' d\omega.
\end{aligned}$$

Finally, in view of (10), it is easy to check that $\mathcal{E}_0 \subset \text{Ker}(Q_1^{el})$, and writing $f = \langle f \rangle + r$, we immediately get

$$\begin{aligned} |\mathcal{B}_1(f, f)| &= |(Q_1^{el}(f), f)_{\mathbb{L}}| = |(Q_1^{el}(r), r)_{\mathbb{L}}| \leq \|r\|_{\mathbb{E}} \|Q_1^{el}(r)\|_{\mathbb{F}} \\ &\leq 2\sqrt{M_2} \|r\|_{\mathbb{E}}^2 \\ &\leq 2M_0\sqrt{M_2}N(f - \langle f \rangle)^2. \end{aligned}$$

We can improve this bound, by noticing that, since the average of r vanishes, (34) and (h3) yield

$$\begin{aligned} \|Q_1^{el}(r)\|_{\mathbb{F}}^2 &\leq M_0M_2 \sum_j \gamma_j B_j^{-1} \int_{S^{N-1}} \int_{S^{N-1}} |r_j(\omega') - r_j(\omega)|^2 d\omega' d\omega \\ &\leq M_0M_2 \sum_j \gamma_j B_j^{-1} \left(2\langle r_j^2 \rangle - 2\langle r_j \rangle^2 \right) \\ &\leq 2M_0M_2 \sum_j \gamma_j B_j^{-1} \langle r_j^2 \rangle = 2M_0M_2 N(r)^2, \end{aligned}$$

and therefore

$$\mathcal{B}_1(f, f) \leq \sqrt{2M_0M_2} \|r\|_{\mathbb{E}} N(r) \leq M_0\sqrt{2M_2}N(f - \langle f \rangle)^2.$$

□

A.4 Proof of Corollary 2.

By combining the symmetry condition (h1'') with estimate (h2''), we can dominate $|\mathcal{B}_1(f, f)|$, as given in Proposition 2-ii) by

$$\begin{aligned} &M/2 \sum_{ij} \int_{S^{N-1}} \int_{S^{N-1}} \gamma_i \gamma_j |f_j(\omega') - f_j(\omega)| |f_i(\omega') - f_i(\omega)| d\omega d\omega' \\ &\leq M/2 \sum_{ij} \gamma_i \gamma_j \left(\int_{S^{N-1}} \int_{S^{N-1}} |f_j(\omega') - f_j(\omega)|^2 d\omega d\omega' \right)^{1/2} \\ &\quad \times \left(\int_{S^{N-1}} \int_{S^{N-1}} |f_i(\omega') - f_i(\omega)|^2 d\omega d\omega' \right)^{1/2}. \end{aligned}$$

Since one assumes $\langle f \rangle = 0$, the integral becomes

$$\int_{S^{N-1}} \int_{S^{N-1}} |f_i(\omega') - f_i(\omega)|^2 d\omega d\omega' = 2\langle f_i^2 \rangle.$$

Hence, we get

$$\begin{aligned}
 |\mathcal{B}_1(f, f)| &\leq M \sum_{ij} \gamma_i \gamma_j \langle f_j^2 \rangle^{1/2} \langle f_i^2 \rangle^{1/2} \\
 &\leq M \left(\sum_{ij} \gamma_i B_i^{-1} \langle f_i^2 \rangle \gamma_j B_j^{-1} \langle f_j^2 \rangle \right)^{1/2} \left(\sum_{ij} \gamma_i B_i \gamma_j B_j \right)^{1/2} \\
 &\leq MM_1 \sum_i \gamma_i B_i^{-1} \langle f_i^2 \rangle = MM_1 N(f)^2.
 \end{aligned}$$
