Rapport de recherche n° 3439 — Juin 1998 — 39 pages

Abstract: The problem of optimal filtering is addressed for a signal observed through a possibly nonlinear channel driven by a fractional Brownian motion. An elementary and completely self-contained approach is developed. An appropriate Girsanov type result is proved and a process – equivalent to the innovation process in the usual situation where the observation noise is a Brownian motion – is introduced. Zakai’s approach is partly extended to derive filtering equations when the signal process is a diffusion. The case of conditionally Gaussian linear systems is analyzed. Closed form equations are derived both for the mean of the optimal filter and the conditional variance of the filtering error. The results are explicit in various special cases.

Key-words: Fractional Brownian motion, Girsanov formula, optimal filtering, innovation process, conditionally Gaussian.

Une approche élémentaire pour le filtrage dans des systèmes avec bruit d'observation brownien fractionnaire

Résumé : On considère le problème du filtrage optimal pour des systèmes linéaires et non linéaires avec bruit d'observation brownien fractionnaire. Une approche élémentaire et complètement autocontenue est développée. D'abord on démontre un résultat du type Girsanov et on introduit un processus qui joue ici le rôle que joue le processus d'innovation dans la situation usuelle où le bruit d'observation est un mouvement brownien. Ensuite l'approche de Zakai est partiellement étendue pour obtenir certaines des équations du filtrage lorsque le processus d'état est une diffusion. Enfin, le cas spécifique des systèmes linéaires conditionnellement gaussiens est analysé. Un système d'équations fermé est obtenu pour la moyenne du filtre optimal et la variance conditionnelle de l'erreur de filtrage. Dans divers cas particuliers, les résultats sont complètement explicites.

Mots-clé : Mouvement brownien fractionnaire, formule de Girsanov, filtrage optimal, processus d'innovation, conditionnellement gaussien.

1 Introduction

Numerous theoretical results and successful applications have been already reported about stochastic models and modeling for long-range dependent phenomena (see e.g. Beran [1, 2] and references therein). The fractional Brownian motion (fBm for short), which provides a suitable generalization of the Brownian motion, is one of the simplest stochastic processes exhibiting long-range dependence. It has been widely used as a modeling tool (see e.g. Hurst [10, 11], Mandelbrot and Van Ness [23], Leland *et al.* [19], Norros [24, 25], Coelho and Decreusefond [4], Comte [3] and Dai and Heyde [6]). So in particular linear systems driven by fBm constitute a favorable ground for attempts to extend the classical theory of continuous-time stochastic systems driven by Brownian motions as developed for example in Liptser and Shiryaev [17]. Recently several contributions in this direction have been obtained for instance by Gripenberg and Norros [9] for a prediction problem, by Norros *et al.* [26] and Le Breton [15] for parameter estimation problems.

The filtering problem for systems driven by fBm's has also been studied. Various specific cases were investigated by Kleptsyna *et al.* [12, 13, 14] and Le Breton [15]. Recently it has been addressed in a rather general framework by Coutin and Decreusefond [5], but the special form of involved equations for the system dynamics allowed them to make use only of the classical Girsanov's formula for the Brownian motion. Here the filtering problem is revisited in a simple setting, yet not already covered, for which an appropriate Girsanov type formula for fBm is needed. A quite elementary and completely self-contained approach is developed to derive an explicit solution (see also Le Breton [16] for preliminary results). We consider real-valued continuous processes $X = (X_t, t \in [0, T])$ and $Y = (Y_t, t \in [0, T])$, representing the signal and the observation respectively. The observation equation for the signal X is the following :

$$(1) \quad Y_t = \xi + \int_0^t A(s, X_s) ds + \int_0^t B(s) dW_s, \quad t \in [0, T].$$

Here $W = (W_t, t \in [0, T])$ is a fBm with Hurst parameter $H \in (\frac{1}{2}, 1)$. The coefficients A and B are continuous functions of $[0, T] \times \mathbb{R}$ and $[0, T]$ respectively into \mathbb{R} and B is supposed nonvanishing. Moreover the random initial

condition ξ in (1) is such that the pair (X, ξ) is independent of W and has a given distribution $\mu_{(X, \xi)}$.

Supposing that only Y is observed but one wishes to know X , the classical problem of filtering the signal X at time t from the observation of Y up to time t occurs. The solution to this problem is the conditional distribution π_t of X_t given $\mathcal{Y}_t = \sigma(\{Y_s, 0 \leq s \leq t\})$ which is called the *optimal filter*. The most successful result of this kind, the so-called Kalman-Bucy filter, was obtained for linear systems driven by Brownian motions in early sixties. It was followed by many contributions extending the result to such nonlinear systems. There are now several efficient strategies to deal with the filtering problem, extensively developed for X and Y semimartingales (see e.g. Liptser and Shiryaev [17] and Elliott [8]). The aim of the present work is to show that actually similar developments are possible in the case of fractional Brownian noises.

The paper is organized as follows. At first in Section 2 some notations are fixed and preliminaries about fBm and integration with respect to fBm are discussed. In particular integral transformations which change a fBm to martingales are described. Then in Section 3 an elementary approach is proposed to derive an appropriate Girsanov type formula. This approach, which extends that initiated in [26] and [15, 16], permits to avoid resorting to very elaborated tools as those developed in Decreusefond and Üstünel [7] and used in [5]. In Section 4 a complementary preparation for filtering deals with integral representations of various processes involved in the problem. At this end a process which plays here the role of the innovation process in the classical situation where the noises are Brownian motions is introduced. Then in Section 5 the Girsanov type formula and the representation results are used to derive filtering equations when the signal process is a diffusion. Conditionally Gaussian linear systems are analyzed in Section 6. Closed form equations are derived both for the mean of the optimal filter and the conditional variance of the filtering error.

2 Preliminaries

Here, for some fixed $T > 0$, $W = (W_t, t \in [0, T])$ is a *normalized fractional Brownian motion* on $[0, T]$ with Hurst parameter $H \in (1/2, 1)$ means that W

is a process, defined on some probability space $(\Omega, \mathcal{F}, \mathbb{P})$, with the following properties:

(i) W is a Gaussian process with continuous paths and stationary increments,

(ii) $W_0 = 0$ and $\mathbb{E}W_t = 0$, $\mathbb{E}W_t^2 = t^{2H}$ for all $t \in [0, T]$.

Of course the fBm reduces to the standard Brownian motion when $H = \frac{1}{2}$. Actually the fBm can be obtained as a stochastic integral with respect to a standard Brownian motion (see e.g. Mandelbrot and Van Ness [23], where the fBm was given its name, Samorodnitsky and Taqqu [28], [26] and [7]). Nevertheless the fBm is not a semimartingale (see e.g. Lin [20]) and hence the theory of integration with respect to fBm does not fall into the classical stochastic integration theory. However the special case of a deterministic integrand turns out to be both easy to handle and sufficient for the purpose of the present paper. Both L^2 and pathwise approaches are possible (see e.g. [9] and [26] for an elementary calculation-oriented introduction).

Let us describe briefly the technical framework. Let Γ_H denote the integral operator

$$\Gamma_H f(t) = H(2H - 1) \int_0^T f(s) |s - t|^{2H-2} ds, \quad t \in [0, T],$$

and define the inner product

$$\begin{aligned} \langle\langle f, g \rangle\rangle_H &= \langle\langle f, \Gamma_H g \rangle\rangle \\ (2) \quad &= H(2H - 1) \int_0^T \int_0^T f(s)g(t) |s - t|^{2H-2} ds dt, \end{aligned}$$

where $\langle\langle . \rangle\rangle$ stands for the usual inner product on $L^2([0, T])$. Let L_H^2 be the space of equivalence classes of measurable functions f on $[0, T]$ such that $\langle\langle f, f \rangle\rangle_H < \infty$. Now it is easy to check that the association $\mathbb{1}_{[0, t]} \rightarrow W_t$ can be extended to an isometry between the function space L_H^2 and the Gaussian space generated by the random variables $W_t, t \geq 0$, as the smallest closed linear subspace of $L^2(\Omega, \mathcal{F}, \mathbb{P})$ containing them. For $f \in L_H^2$, the integral $\int_0^T f(s) dW_s$ can now be defined as the image of f in this isometry. Of course, for any f

and g in L^2_H , the following identity holds:

$$(3) \quad \mathbb{E}[\{\int_0^T f(s)dW_s\}\{\int_0^T g(t)dW_t\}] = \langle\langle f, g \rangle\rangle_H,$$

where $\langle\langle f, g \rangle\rangle_H$ is given by (2). Actually if the function f is of bounded variation, then the integral $\int_0^T f(s)dW_s(\omega)$ can be defined for almost all ω 's as a limit of Riemann sums, and it is easy to see that the integral obtained coincides with the L^2 integral almost surely. The convergence of these Riemann sums is equivalent to that of the Riemann-Stieltjes type integral appearing in the right hand side of the integration by parts formula

$$\int_0^T f(s)dW_s = f(T)W_T - \int_0^T W_s df(s),$$

and thus guaranteed by the continuity of the sample paths of W . Much stronger results (cf. e.g. Lyons [22]) can be obtained using more precise properties of the sample paths of the fBm. Of course, for an appropriate function f , the stochastic process $(\int_0^t f(s)dW_s, t \in [0, T])$, integral of f with respect to W , is then defined by

$$\int_0^t f(s)dW_s \triangleq \int_0^T \mathbb{1}_{[0,t)}(s)f(s)dW_s, \quad t \in [0, T],$$

and a continuous version of this process can be chosen, what shall be always done in the sequel.

Although the fBm is not a semimartingale, simple integral transformations which change it to martingales can be identified. To prove a Girsanov type formula in the next section, we shall make use of the following technical result which was shown in [15] with slightly different notations (see also [26] for a particular case). In the sequel Γ stands for the gamma function.

Lemma 1 *Let W be a fBm with Hurst parameter $H \in (1/2, 1)$. Let C be a continuous function of $[0, T]$ into \mathbb{R} . Define for $0 < t \leq T$ the function $k_C^t = (k_C^t(s), 0 < s < t)$ by*

$$(4) \quad k_C^t(s) \triangleq -\rho_H^{-1} s^{\frac{1}{2}-H} \frac{d}{ds} \int_s^t dw w^{2H-1} (w-s)^{\frac{1}{2}-H} \frac{d}{dw} \int_0^w dz z^{\frac{1}{2}-H} (w-z)^{\frac{1}{2}-H} C(z),$$

where $\rho_H = \Gamma^2(\frac{3}{2} - H)\Gamma(2H + 1)\sin(\pi H)$. Then the function k_C^t satisfies the equation

$$(5) \quad H(2H - 1) \int_0^t k_C^t(s) |s - r|^{2H-2} ds = C(r); \quad 0 < r < t.$$

Define for $0 \leq t \leq T$

$$(6) \quad N_t^C \triangleq \int_0^t k_C^t(s) dW_s; \quad \langle N^C \rangle_t \triangleq \int_0^t C(s) k_C^t(s) ds.$$

Then the process $N^C = (N_t^C, 0 \leq t \leq T)$ is a Gaussian martingale and the function $\langle N^C \rangle = (\langle N^C \rangle_t, t \in [0, T])$ is its variance function.

Remark 1 (a) Let us mention that the definition (4) of the function k_C^t can be interpreted in terms of right and left fractional derivatives $\mathcal{D}_{0+}^{H-\frac{1}{2}}$ and $\mathcal{D}_{t-}^{H-\frac{1}{2}}$ (see Samko *et al.* [27]) :

$$k_C^t(s) = [\Gamma(2H + 1)\sin(\pi H)]^{-1} s^{\frac{1}{2}-H} \mathcal{D}_{t-}^{H-\frac{1}{2}} s^{2H-1} \mathcal{D}_{0+}^{H-\frac{1}{2}} s^{\frac{1}{2}-H} C(s); \quad 0 < s < t.$$

(b) In particular, for $C \equiv 1$ the function k_C^t is (see [26] or [15]) :

$$(7) \quad k_*^t(s) = \kappa_H^{-1} s^{\frac{1}{2}-H} (t-s)^{\frac{1}{2}-H}, \quad 0 < s < t,$$

with

$$\kappa_H = 2H\Gamma(\frac{3}{2} - H)\Gamma(H + \frac{1}{2}).$$

Then the corresponding Gaussian martingale (called in [26] the “fundamental martingale” associated to the fBm W) is

$$(8) \quad N_t^* = \kappa_H^{-1} \int_0^t s^{\frac{1}{2}-H} (t-s)^{\frac{1}{2}-H} dW_s, \quad t \in [0, T],$$

and it has the variance function

$$(9) \quad \langle N^* \rangle_t = \kappa_H^{-1} \int_0^t s^{\frac{1}{2}-H} (t-s)^{\frac{1}{2}-H} ds = \lambda_H^{-1} t^{2-2H}, \quad t \in [0, T],$$

where

$$\lambda_H = \frac{2H\Gamma(3 - 2H)\Gamma(H + \frac{1}{2})}{\Gamma(\frac{3}{2} - H)}.$$

The following property, which is proved in [26], will be a key point in our developments below : the filtration generated by the martingale N^* coincides with that generated by the fBm W up to sets of \mathbb{P} probability zero.

(c) If C and D are two continuous functions of $[0, T]$ into \mathbb{R} and processes N^C and N^D correspond to C and D respectively by (6), then of course the pair (N^C, N^D) is Gaussian; actually, from (3) and (5), one may easily check that it is a martingale with the covariance function

$$\langle N^C, N^D \rangle_t = \int_0^t k_C^t(s)D(s)ds = \int_0^t k_D^t(s)C(s)ds, \quad t \in [0, T].$$

In particular

$$(10) \quad \langle N^C, N^* \rangle_t = \int_0^t k_C^t(s)ds = \int_0^t k_*^t(s)C(s)ds, \quad t \in [0, T].$$

(d) Let us observe that when $H = \frac{1}{2}$, i.e. W is a standard Brownian motion, then assertions in Lemma 1 reduce to elementary facts concerning the Itô stochastic integral with respect to W . Actually in this case

$$k_C^t \equiv C; \quad N_t^C = \int_0^t C(s)dW_s; \quad \langle N^C \rangle_t = \int_0^t C^2(s)ds,$$

and in particular $k_*^t \equiv 1$, $N_t^* = W_t$, $\langle N^* \rangle_t = t$.

Now we state some useful complementary properties of martingales defined as in Lemma 1.

Lemma 2 *Let assumptions and notations be the same as in Lemma 1. Let also N^* be the martingale defined by (8) and $\langle N^* \rangle$ be its variance function defined by (9). Then the martingale N^C defined by (6) is continuous. Moreover there exists a measurable function $q^C = (q_t^C, t \in [0, T])$ such that*

$$\int_0^T (q_t^C)^2 d \langle N^* \rangle_t < +\infty,$$

and the representations

$$(11) \quad N_t^C = \int_0^t q_s^C dN_s^*; \quad \langle N^C \rangle_t = \int_0^t (q_s^C)^2 d \langle N^* \rangle_s, \quad t \in [0, T],$$

hold.

Proof At first let us discuss the continuity property of N^C . Since from Lemma 1 N^C is a Gaussian martingale, it is sufficient to show that its variance function $\langle N^C \rangle$ is continuous. Actually this can be easily proved starting from the definition (6) of this function and the formula (4) for the involved function k_C^t .

Of course in particular N^* is continuous. Moreover, from Remark 1(b), N^* generates the same filtration as the fBm W up to sets of \mathbb{P} probability zero. Therefore, since N^C is clearly adapted to the last filtration, it is also adapted to the filtration generated by N^* . Consequently, since from Remark 1(c) the pair (N^C, N^*) is a Gaussian martingale, we may apply the generalized Kalman filter derived in Liptser and Shiryaev [18] (see Problem 2, p. 320) and hence get that the representations (11) hold with

$$(12) \quad q_t^C = \frac{d \langle N^C, N^* \rangle_t}{d \langle N^* \rangle_t}, \quad t \in [0, T],$$

where $\langle N^C, N^* \rangle$ is the covariance function of (N^C, N^*) given by (10). \blacksquare

Remark 2 (a) Let us observe that, taking into account (9), an immediate consequence of equation (12) is that the function $\langle N^C, N^* \rangle$ given by (10) is absolutely continuous with respect to the Lebesgue measure with the derivative $t \rightarrow \lambda_H^{-1}(2-2H)t^{1-2H}q_t^C$. Moreover, due to the expression (7) of the function k_*^t , this derivative can be seen also as the right fractional derivative $\mathcal{D}_{0+}^{H-\frac{1}{2}}$ (see [27]) of the function $t \rightarrow [2H\Gamma(H+\frac{1}{2})]^{-1}t^{\frac{1}{2}-H}C(t)$. Finally we can write

$$(13) \quad \int_0^t k_*^t(s)C(s)ds = \int_0^t q_s^C d \langle N^* \rangle_s, \quad t \in [0, T],$$

where

$$q_t^C = \frac{\Gamma(2-2H)}{\Gamma(\frac{3}{2}-H)} t^{2H-1} \mathcal{D}_{0+}^{H-\frac{1}{2}} t^{\frac{1}{2}-H} C(t), \quad t \in [0, T].$$

(b) More generally, for any fixed $u \in (0, T)$, we can write

$$(14) \quad \int_u^t k_*^t(s)C(s)ds = \int_u^t q^C(s, u) d \langle N^* \rangle_s, \quad t \in [u, T],$$

where

$$q^C(t, u) = \frac{\Gamma(2-2H)}{\Gamma(\frac{3}{2}-H)} t^{2H-1} \mathcal{D}_{u+}^{H-\frac{1}{2}} t^{\frac{1}{2}-H} C(t), \quad t \in [u, T].$$

Hence in the sequel we shall use the notation $q^C(t, 0)$ for q_t^C .

(c) Let us also mention that when $H = \frac{1}{2}$, i.e. W is a standard Brownian motion, then of course the assertion in Lemma 2 reduces to a triviality with $q^C \equiv C$. Actually in this case, with the notation of Remark (b) just above, we have more generally $q^C(., u) \equiv C$.

Now we turn to some complementary preparation for studying the filtering problem.

3 A Girsanov type formula

There is now a quite usual strategy to deal with the filtering problem, extensively developed for X and Y semimartingales, i.e. when in particular the observation noise W in (1) is a Brownian motion which means $H = \frac{1}{2}$. The first step consists in constructing a new probability measure $\tilde{\mathbb{P}}$, called the reference probability, a $\tilde{\mathbb{P}}$ Brownian motion carrying the same filtration as the observation process and such that under $\tilde{\mathbb{P}}$, it is independent of the signal process. The second step is to show that the optional projection under \mathbb{P} can be transformed to a $\tilde{\mathbb{P}}$ conditional expectation to obtain an equation for

$$\pi_t(\phi) \triangleq \mathbb{E}(\phi(X_t) | \mathcal{Y}_t),$$

for sufficiently regular function ϕ from \mathbb{R} to \mathbb{R} . We shall show that in the situation which we are dealing with here a similar approach can be led. A key point is the construction of the appropriate reference probability which relies on a Girsanov type result. In [7], Girsanov's formula was derived in a very general framework for changes of measure in a stochastic basis with fBm by making use of rather sophisticated tools. Here, due to our simple setting, we may develop an elementary approach which leads to quite explicit results (see [26] and [15, 16] for more specific cases).

Actually in the sequel it is convenient to work on the canonical space of the process (X, Y) . Let $\Omega = \mathcal{C}([0, T]; \mathbb{R}^2)$ be the space of continuous functions from $[0, T]$ into \mathbb{R}^2 . Consider also the canonical process $(X, W^*) = ((X_t, W_t^*), t \in [0, T])$ on Ω where $(X_t, W_t^*)(x, y) = (x_t, y_t)$ for any $(x, y) \in \Omega$.

Hereafter $\tilde{\mathbb{P}}$ denotes the unique probability measure on Ω such that defining the variable ξ by

$$\xi = W_0^*,$$

and the process $\tilde{W} = (\tilde{W}_t), t \in [0, T]$ by

$$\tilde{W}_t = W_t^* - W_0^*, t \in [0, T],$$

the following properties hold :

- the pair (X, ξ) is independent of \tilde{W} and has the distribution $\mu_{(X, \xi)}$,
- the process \tilde{W} is a fBm with Hurst parameter H .

The canonical filtration on Ω is $(\mathcal{F}_t, t \in [0, T])$ where $\mathcal{F}_t = \sigma(\{(X_s, W_s^*), 0 \leq s \leq t\}) \vee \mathcal{N}$, \mathcal{N} denoting the set of null sets of $(\Omega, \tilde{\mathbb{P}})$.

Let us define for all continuous function $x = (x_t, t \in [0, T])$ the function $C(x)$ on $[0, T]$ by

$$(15) \quad C(x)(t) \triangleq \frac{A(t, x_t)}{B(t)}, t \in [0, T].$$

Consider, for any $t \in [0, T]$, the function $k_{C(x)}^t = (k_{C(x)}^t(s), 0 < s < t)$ defined from equation (4) with $C(x)$ in place of C . Define also the process $\tilde{N}(x) = (\tilde{N}_t(x), t \in [0, T])$ by

$$(16) \quad \tilde{N}_t(x) \triangleq \int_0^t k_{C(x)}^t(s) d\tilde{W}_s, t \in [0, T],$$

and the function $\langle \tilde{N} \rangle (x) = (\langle \tilde{N} \rangle_t (x), t \in [0, T])$ by

$$(17) \quad \langle \tilde{N} \rangle_t (x) \triangleq \int_0^t k_{C(x)}^t(s) C(x)(s) ds, t \in [0, T],$$

which actually is nothing but $\langle N^{C(x)} \rangle$ defined from the second part of (6) with $C(x)$ in place of C .

Observe that from Lemma 1, under $\tilde{\mathbb{P}}$ the process $\tilde{N}(x)$ is a Gaussian martingale with the variance function $\langle \tilde{N} \rangle (x)$. Then of course defining for all $t \in [0, T]$

$$(18) \quad \Lambda_t(x) \triangleq \exp\{\tilde{N}_t(x) - \frac{1}{2} \langle \tilde{N} \rangle_t (x)\},$$

the following equality holds :

$$(19) \quad \tilde{\mathbb{E}}(\Lambda_t(x)) = 1.$$

Finally, for any $t \in [0, T]$, we introduce the random variables

$$(20) \quad \tilde{N}_t \triangleq \tilde{N}_t(X); \quad \langle \tilde{N} \rangle_t \triangleq \langle \tilde{N} \rangle_t(X),$$

and

$$(21) \quad \Lambda_t \triangleq \Lambda_t(X) = \exp\{\tilde{N}_t - \frac{1}{2} \langle \tilde{N} \rangle_t\}.$$

Let us emphasize that actually for each t the variables N_t , $\langle N \rangle_t$ and Λ_t depend only on values of X in the past of time t i.e. for instance $N_t = N_t(X^{(t)})$ where $X^{(t)} = (X_s, 0 \leq s \leq t)$. Now, since under $\tilde{\mathbb{P}}$ the processes X and \tilde{W} are independent, making use of identity (19), it is readily seen that $\tilde{\mathbb{E}}(\Lambda_t) = 1$ and $\tilde{\mathbb{E}}(\Lambda_T | \mathcal{F}_t) = \Lambda_t$ for all $t \in [0, T]$. Hence we may define the probability \mathbb{P} which is absolutely continuous with respect to $\tilde{\mathbb{P}}$ with the Radon-Nikodym derivative Λ_T , so that for any $t \in [0, T]$ the local density process on the family $\{\mathcal{F}_t, t \in [0, T]\}$ is nothing but $(\Lambda_t, t \in [0, T])$.

Now, defining on $(\Omega, (\mathcal{F}_t), \tilde{\mathbb{P}})$ the process $W = (W_t, t \in [0, T])$ by

$$(22) \quad W_t \triangleq \tilde{W}_t - \int_0^t C(X)(s)ds, \quad t \in [0, T],$$

and considering the continuous adapted process $Y = (Y_t, t \in [0, T])$ given by :

$$(23) \quad Y_t = \xi + \int_0^t B(s)d\tilde{W}_s, \quad t \in [0, T].$$

we may state the following Girsanov type result :

Proposition 1 *Let \mathbb{P} be the probability measure $\mathbb{P} \triangleq \Lambda_T \cdot \tilde{\mathbb{P}}$ where Λ_T is given by (21). Then, under \mathbb{P} , the distribution of the system (X, ξ, W) , where W is defined by (22), is the same as that of the system (X, ξ, \tilde{W}) under $\tilde{\mathbb{P}}$. Moreover under \mathbb{P} the process Y defined by (23) satisfies the equation (1).*

Proof To prove the first assertion it is sufficient to show that for any fixed $0 \leq t_1 < t_2 \dots < t_n \leq T$, the distribution of $(X, \xi, W_{t_1}, \dots, W_{t_n})$ with respect to \mathbb{P} is that of $(X, \xi, \widetilde{W}_{t_1}, \dots, \widetilde{W}_{t_n})$ with respect to $\widetilde{\mathbb{P}}$. So we fix Borel sets Γ and Δ in $C([0, T]; \mathbb{R})$ and \mathbb{R} respectively and a vector $\beta = (\beta_1, \dots, \beta_n)'$ in \mathbb{R}^n . We have to check that

$$(24) \quad \mathbb{E}\left(\mathbf{1}_{\Gamma \times \Delta}(X, \xi) \exp\left(\sum_1^n \beta_i W_{t_i}\right)\right) = \mu_{(X, \xi)}(\Gamma \times \Delta) \exp\left(\frac{1}{2}[\beta' \Sigma_H^{(n)} \beta]\right),$$

where $\Sigma_H^{(n)}$ stands for the covariance matrix of $(\widetilde{W}_{t_1}, \dots, \widetilde{W}_{t_n})'$ with respect to $\widetilde{\mathbb{P}}$. By definitions (22) and (21) of W and Λ_T respectively, from $\mathbb{P} = \Lambda_T \cdot \widetilde{\mathbb{P}}$ we compute the left hand side of (24) (lhs(24) for short) as

$$\widetilde{\mathbb{E}}\left(\mathbf{1}_{\Gamma \times \Delta}(X, \xi) \exp\left\{\sum_1^n \beta_i \widetilde{W}_{t_i} - \sum_1^n \beta_i \int_0^{t_i} C(X)(u) du + \widetilde{N}_T - \frac{1}{2} \langle \widetilde{N} \rangle_T\right\}\right).$$

Then, taking into account the independence of (X, ξ) and \widetilde{W} with respect to $\widetilde{\mathbb{P}}$, it comes that

$$(25) \quad \text{lhs}(24) = \widetilde{\mathbb{E}}\left(\mathbf{1}_{\Gamma \times \Delta}(X, \xi) [\widetilde{\mathbb{E}}(\exp(U(x)))]_{|x=X}\right),$$

where, for a continuous function x of $[0, T]$ into \mathbb{R} , $U(x)$ is the random variable

$$U(x) = \sum_1^n \beta_i \widetilde{W}_{t_i} - \sum_1^n \beta_i \int_0^{t_i} C(x)(u) du + \widetilde{N}_T(x) - \frac{1}{2} \langle \widetilde{N} \rangle_T(x),$$

with $\widetilde{N}_T(x)$ and $\langle \widetilde{N} \rangle_T(x)$ given by (16) and (17) respectively. With respect to $\widetilde{\mathbb{P}}$ the random variable $U(x)$ is Gaussian with mean

$$(26) \quad \widetilde{\mathbb{E}}(U(x)) = - \sum_1^n \beta_i \int_0^{t_i} C(x)(u) du - \frac{1}{2} \langle \widetilde{N} \rangle_T(x),$$

and variance

$$\widetilde{\text{var}}(U(x)) = \widetilde{\mathbb{E}}[(\widetilde{N}_T(x))^2] + \widetilde{\mathbb{E}}\left[\left(\sum_1^n \beta_i W_{t_i}\right)^2\right] + 2 \sum_1^n \beta_i \widetilde{\mathbb{E}}(\widetilde{N}_T(x) \widetilde{W}_{t_i}),$$

or

$$\widetilde{\text{var}}(U(x)) = \langle \widetilde{N} \rangle_T(x) + \beta' \Sigma_H^{(n)} \beta + 2 \sum_1^n \beta_i \widetilde{\mathbb{E}}(\widetilde{N}_T(x) \widetilde{W}_{t_i}).$$

But, from identity (3), definition (16) of $\widetilde{N}_T(x)$ and equation (5), it is easy to check that

$$\widetilde{\mathbb{E}}(\widetilde{N}_T(x)\widetilde{W}_{t_i}) = \int_0^{t_i} C(x)(u)du.$$

Finally we get

$$(27) \quad \widetilde{var}(U(x)) = \langle \widetilde{N} \rangle_T(x) + \beta' \Sigma^{(n)} \beta + 2 \sum_1^n \beta_i \int_0^{t_i} C(x)(u)du.$$

But, since under $\widetilde{\mathbb{P}}$ the variable $U(x)$ is Gaussian, we have

$$\widetilde{\mathbb{E}}[\exp(U(x))] = \exp[\widetilde{\mathbb{E}}(U(x) + \frac{1}{2}\widetilde{var}(U(x))].$$

Hence, from equations (26) and (27), it is readily seen that

$$\widetilde{\mathbb{E}}[\exp(U(x))] = \exp(\frac{1}{2}\beta' \Sigma_H^{(n)} \beta),$$

and inserting this in (25) we obtain that

$$\text{lhs}(24) = [\widetilde{\mathbb{E}}(\mathbb{1}_{\Gamma \times \Delta}(X, \xi))] \exp(\frac{1}{2}\beta' \Sigma_H^{(n)} \beta),$$

which means that the equality (24) holds.

Finally the second assertion in the statement is a straightforward consequence of the first one and of definition (22) of the process W . \blacksquare

We remind now the usual notations which we use hereafter :

- $\mathcal{Y}_t = \sigma(\{Y_s, 0 \leq s \leq t\})$, $t \in [0, T]$,
- $\pi_t(\phi) = \mathbb{E}[\phi(X_t) | \mathcal{Y}_t]$; $\sigma_t(\phi) = \widetilde{\mathbb{E}}[\phi(X_t)\Lambda_t | \mathcal{Y}_t]$, $t \in [0, T]$.

The distribution π_t is the *optimal filter* (when observation is made on $[0, t]$) whereas the measure σ_t is the so-called *unnormalized filter*. They both operate on bounded continuous real-valued functions and the well-known Bayes type formula, called the Kallianpur-Striebel formula, holds : for all $t \in [0, T]$, $\widetilde{\mathbb{P}}$ and \mathbb{P} almost everywhere,

$$(28) \quad \pi_t(\phi) = \frac{\sigma_t(\phi)}{\sigma_t(1)}.$$

Actually, more generally, for a sufficiently regular function ψ_t on the set $\mathcal{C}([0, t]; \mathbb{R})$ of continuous functions on $[0, t]$, we shall also be concerned with similar quantities with the variable $\psi_t(X^{(t)})$, written simply $\psi_t(X)$, in place of $\phi(X_t)$, where $X^{(t)}$ stands for the process $X^{(t)} = (X_s, 0 \leq s \leq t)$. So for instance the notation $\pi_t(\psi)$ will also be used for the conditional expectation $\mathbb{E}[\psi_t(X) \mid \mathcal{Y}_t]$.

4 The innovation type process

Here we deal with integral representations of various processes involved in the filtering problem. We start with the processes $N = (N_t, t \in [0, T])$ and $\langle N \rangle = (\langle N \rangle_t, t \in [0, T])$ defined from (6) by plugging in the process $C(X)$ in place of C i.e.

$$(29) \quad N_t \triangleq N_t^{C(X)}; \quad \langle N \rangle_t \triangleq \langle N^{C(X)} \rangle_t, \quad t \in [0, T].$$

Notice that here again actually N_t and $\langle N \rangle_t$ depend only on values of $X^{(t)} = (X_s, 0 \leq s \leq t)$.

Recall the martingale N^* and the function $\langle N^* \rangle$ defined in Remark 1(b) by (8) and (9) respectively i.e.

$$(30) \quad N_t^* \triangleq \int_0^t k_*^t(s) dW_s; \quad \langle N^* \rangle_t \triangleq \int_0^t k_*^t(s) ds, \quad t \in [0, T],$$

where the function k_*^t is given by (7).

Now let us define the (\mathcal{F}_t) -adapted processes $\langle N, N^* \rangle = (\langle N, N^* \rangle_t, t \in [0, T])$ and $q(X) = (q_t(X), t \in [0, T])$ from (10) and (12) respectively by

$$(31) \quad \langle N, N^* \rangle_t \triangleq \langle N^{C(X)}, N^* \rangle_t = \int_0^t k_*^t(s) C(X)(s) ds, \quad t \in [0, T],$$

and

$$(32) \quad q_t(X) \triangleq q_t^{C(X)} = \frac{d \langle N, N^* \rangle_t}{d \langle N^* \rangle_t}, \quad t \in [0, T].$$

Applying Lemma 2, substituting $C(X)$ to C , it is readily seen that \mathbb{P} almost surely

$$\int_0^T q_t^2(X) d \langle N^* \rangle_t < +\infty,$$

and the representations

$$(33) \quad N_t = \int_0^t q_s(X) dN_s^*; \quad \langle N \rangle_t = \int_0^t q_s^2(X) d \langle N^* \rangle_s, \quad t \in [0, T],$$

hold.

Now we introduce the process Z defined by

$$(34) \quad Z_t \triangleq \int_0^t k_{C(X)}^t(s) B^{-1}(s) dY_s, \quad t \in [0, T],$$

where Y is the observation process.

Finally we define the process Z^* by

$$(35) \quad Z_t^* \triangleq \int_0^t k_*^t(s) B^{-1}(s) dY_s, \quad t \in [0, T],$$

where the function k_*^t is given by (7).

Under \mathbb{P} , since from (1) $dY_t = A(t, X_t)dt + B(t)dW_t$, the process Z^* appears as a semimartingale with the following decomposition :

$$(36) \quad Z_t^* = \langle N, N^* \rangle_t + N_t^*, \quad t \in [0, T],$$

where N^* is given by (30) and $\langle N, N^* \rangle$ is defined from (31).

Similarly the process Z appears as a semimartingale with the decomposition :

$$(37) \quad Z_t = \langle N \rangle_t + N_t, \quad t \in [0, T],$$

where N and $\langle N \rangle$ are given by (29). Now from (33), (32) and (36)-(37) we can write

$$(38) \quad Z_t^* = \int_0^t q_s(X) d \langle N^* \rangle_s + N_t^*, \quad t \in [0, T],$$

and

$$Z_t = \int_0^t q_s^2(X) d \langle N^* \rangle_s + \int_0^t q_s(X) dN_s^*, \quad t \in [0, T].$$

Hence finally we get the following integral representation of Z in terms of Z^* :

$$(39) \quad Z_t = \int_0^t q_s(X) dZ_s^*, \quad t \in [0, T].$$

Now let us introduce the process $\nu = (\nu_t, t \in [0, T])$ defined by

$$(40) \quad \nu_t = Z_t^* - \int_0^t \pi_s(q) d \langle N^* \rangle_s, \quad t \in [0, T],$$

as a candidate to play the role which plays the *innovation process* in the usual situation where the noises are Brownian motions. Recall the notation $\pi_s(q) = \mathbb{E}(q_s(X)|\mathcal{Y}_s)$. We prove the following

Lemma 3 *Let processes Z^* and ν be defined by (35) and (40) respectively. Let the function $\langle N^* \rangle$ be given by (30) or (9). For $t \in [0, T]$, let \mathcal{F}_t^{ξ, Z^*} denote the σ -field $\mathcal{F}_t^{\xi, Z^*} = \sigma(\{\xi; Z_s^*, 0 \leq s \leq t\})$. Then the following assertions hold :*

(i) *for all $t \in [0, T]$, the σ -fields \mathcal{F}_t^{ξ, Z^*} and \mathcal{Y}_t coincide up to sets of \mathbb{P} probability zero,*

(ii) *under \mathbb{P} , the process ν is a continuous Gaussian (\mathcal{Y}_t) -martingale with the variance function $\langle N^* \rangle$,*

(iii) *if $M = (M_t, t \in [0, T])$ is a square integrable (\mathcal{Y}_t) -martingale with respect to \mathbb{P} , $M_0 = 0$, then there exists a (\mathcal{Y}_t) -adapted process $\Gamma = (\Gamma_t, t \in [0, T])$ such that*

$$\mathbb{E}[\int_0^T \Gamma_t^2 d \langle N^* \rangle_t] < +\infty,$$

and \mathbb{P} almost surely

$$M_t = \int_0^t \Gamma_s d\nu_s, \quad t \in [0, T].$$

Proof At first let us prove assertion (i). Observe that under $\tilde{\mathbb{P}}$, since $dY_s = B(s)d\tilde{W}_s$ and B is nonvanishing, we have $\mathcal{Y}_t = \sigma(\{\xi; \tilde{W}_s, 0 \leq s \leq t\})$ up to sets of $\tilde{\mathbb{P}}$ probability zero. But, under $\tilde{\mathbb{P}}$, we have also almost surely

$$Z_t^* = \int_0^t k_*^t(s) d\tilde{W}_s, \quad t \in [0, T].$$

Then, from Remark 1(b), Z^* generates the same filtration as \tilde{W} up to sets of $\tilde{\mathbb{P}}$ probability zero. Hence $\mathcal{Y}_t = \mathcal{F}_t^{\xi, Z^*}$ up to sets of $\tilde{\mathbb{P}}$ probability zero.

Consequently, since \mathbb{P} is equivalent to $\tilde{\mathbb{P}}$, assertion (i) holds. Now we turn to assertion (ii). From (40) and (38) we can write

$$\nu_t = \int_0^t [q_s(X) - \pi_s(q)] d \langle N^* \rangle_s + N_t^*, \quad t \in [0, T].$$

Therefore, for $0 \leq s \leq t \leq T$ we have

$$\nu_t - \nu_s = \int_s^t [q_u(X) - \pi_u(q)] d \langle N^* \rangle_u + [N_t^* - N_s^*].$$

Then, exploiting the fact that $\langle N^* \rangle$ is deterministic, the conditional expectation $\mathbb{E}[\nu_t - \nu_s \mid \mathcal{Y}_s]$ can be computed as

$$\mathbb{E}[\int_s^t \mathbb{E}[q_u(X) - \pi_u(q) \mid \mathcal{Y}_u] d \langle N^* \rangle_u \mid \mathcal{Y}_s] + \mathbb{E}[\mathbb{E}(N_t^* - N_s^* \mid \mathcal{F}_s) \mid \mathcal{Y}_s].$$

Now using the $((\mathcal{F}_t), \mathbb{P})$ -martingale property of N^* we get that

$$\mathbb{E}[\nu_t - \nu_s \mid \mathcal{Y}_s] = 0, \quad \mathbb{P} \text{ almost surely,}$$

which gives that under \mathbb{P} , the process ν is a (\mathcal{Y}_t) -martingale. Moreover, with respect to the filtration (\mathcal{F}_t) , ν is a continuous semimartingale. Hence, by the differentiation rule, we have the decomposition

$$\nu_t^2 = 2 \int_0^t \nu_s d\nu_s + \langle N^* \rangle_t, \quad t \in [0, T].$$

This shows that, with respect to the filtration (\mathcal{F}_t) , the predictable quadratic variation of ν is nothing but the continuous deterministic function $\langle N^* \rangle$. Consequently, with respect to the filtration (\mathcal{Y}_t) , the predictable quadratic variation of ν is also $\langle N^* \rangle$ and thus the continuous $((\mathcal{Y}_t), \mathbb{P})$ -martingale ν is necessarily Gaussian with the variance function $\langle N^* \rangle$.

Finally let us prove assertion (iii) in the lemma. From (40) we have

$$Z_t^* = \int_0^t \pi_s(q) d \langle N^* \rangle_s + \nu_t, \quad t \in [0, T],$$

where $\pi_s(q)$ is (\mathcal{Y}_t) -adapted and, from (ii), ν is a continuous Gaussian $((\mathcal{Y}_t), \mathbb{P})$ -martingale such that $\langle \nu \rangle = \langle N^* \rangle$. Now let us define the $((\mathcal{Y}_t), \mathbb{P})$ -martingale $\Lambda^* = (\Lambda_t^*, t \in [0, T])$ by

$$(41) \quad \Lambda_t^* = \exp \left\{ - \int_0^t \pi_s(q) d\nu_s - \frac{1}{2} \int_0^t \pi_s^2(q) d \langle N^* \rangle_s \right\}, \quad t \in [0, T],$$

and the probability measure \mathbb{P}^* on Ω as $\mathbb{P}^* = \Lambda_T^* \cdot \mathbb{P}$. Then, from the standard Girsanov theorem, the process Z^* is a continuous Gaussian $((\mathcal{Y}_t), \mathbb{P}^*)$ -martingale such that $\langle Z^* \rangle = \langle N^* \rangle$.

Hence if $M^* = (M_t^*, t \in [0, T])$ is a $((\mathcal{Y}_t), \mathbb{P}^*)$ -martingale, $M_0^* = 0$, there exists a (\mathcal{Y}_t) -adapted process $g = (g_t, t \in [0, T])$ such that \mathbb{P}^* almost surely

$$(42) \quad M_t^* = \int_0^t g_s dZ_s^*, \quad t \in [0, T].$$

Now if M is a $((\mathcal{Y}_t), \mathbb{P})$ -martingale, $M_0 = 0$, the process M^* defined by

$$M_t^* = \Lambda_t^{*-1} M_t, \quad t \in [0, T],$$

is a $((\mathcal{Y}_t), \mathbb{P}^*)$ -martingale, $M_0^* = 0$. Hence it admits a representation of type (42), so that \mathbb{P} almost surely

$$M_t^* = \int_0^t g_s \pi_s(q) d \langle N^* \rangle_s + \int_0^t g_s d\nu_s, \quad t \in [0, T].$$

Since from (41) we have

$$\Lambda_t^* = 1 - \int_0^t \Lambda_s^* \pi_s(q) d\nu_s, \quad t \in [0, T],$$

applying the Itô formula, for $t \in [0, T]$, we compute M_t as $M_t = \Lambda_t^* M_t^*$:

$$\begin{aligned} M_t &= \int_0^t M_s^* d\Lambda_s^* + \int_0^t \Lambda_s^* dM_s^* + \langle \Lambda^*, M^* \rangle_t \\ &= - \int_0^t M_s^* \Lambda_s^* \pi_s(q) d\nu_s + \int_0^t \Lambda_s^* g_s \pi_s(q) d \langle N^* \rangle_s \\ &\quad + \int_0^t \Lambda_s^* g_s d\nu_s - \int_0^t \Lambda_s^* g_s \pi_s(q) d \langle N^* \rangle_s \\ &= \int_0^t \Lambda_s^* [g_s - M_s^* \pi_s(q)] d\nu_s. \end{aligned}$$

This means that assertion (iii) holds. ■

We end the present section by providing a representation of the conditional expectation $\hat{\zeta}_t = \mathbf{E}[\zeta_t \mid \mathcal{Y}_t]$ for a $((\mathcal{F}_t), \mathbb{P})$ -semimartingale $\zeta = (\zeta_t, t \in [0, T])$ as the solution of some stochastic differential equation.

Proposition 2 Let $\zeta = (\zeta_t, t \in [0, T])$ be a $((\mathcal{F}_t), \mathbb{P})$ -semimartingale of the form

$$\zeta_t = \zeta_0 + \int_0^t \beta_s ds + m_t, \quad t \in [0, T],$$

where $\mathbb{E}[\zeta_0^2] < +\infty$, $\mathbb{E}[\int_0^T \beta_t^2 dt] < +\infty$ and $m = (m_t, t \in [0, T])$ is a square integrable $((\mathcal{F}_t), \mathbb{P})$ -martingale such that $\langle m, N^* \rangle_t = \int_0^t \lambda_s ds < N^* \rangle_s, t \in [0, T]$. Then the process $\hat{\zeta} = (\hat{\zeta}_t, t \in [0, T])$ satisfies the stochastic differential equation

$$(43) \quad \hat{\zeta}_t = \hat{\zeta}_0 + \int_0^t \hat{\beta}_s ds + \int_0^t [\hat{\lambda}_s + \zeta_s \widehat{q}_s(X) - \hat{\zeta}_s \pi_s(q)] d\nu_s, \quad t \in [0, T].$$

where $q(X)$ is the process defined by (32), $\hat{\beta}_s = \mathbb{E}[\beta_s | \mathcal{Y}_s]$, $\hat{\lambda}_s = \mathbb{E}[\lambda_s | \mathcal{Y}_s]$, $\zeta_s \widehat{q}_s(X) = \mathbb{E}[\zeta_s q_s(X) | \mathcal{Y}_s]$ and ν is given by (40).

Proof The proof parallels that of Theorem 18.11 in [8]. Define the process $M = (M_t, t \in [0, T])$ by

$$M_t = \hat{\zeta}_t - \hat{\zeta}_0 - \int_0^t \hat{\beta}_s ds, \quad t \in [0, T].$$

Then for $0 \leq s \leq t \leq T$ we have

$$\mathbb{E}[M_t - M_s | \mathcal{Y}_s] = \mathbb{E}[\hat{\zeta}_t - \hat{\zeta}_s - \int_s^t \hat{\beta}_u du | \mathcal{Y}_s].$$

However we have

$$\begin{aligned} \mathbb{E}[\hat{\zeta}_t - \hat{\zeta}_s | \mathcal{Y}_s] &= \mathbb{E}[\zeta_t - \zeta_s | \mathcal{Y}_s] \\ &= \mathbb{E}\left[\int_s^t \beta_u du | \mathcal{Y}_s\right] + \mathbb{E}[m_t - m_s | \mathcal{Y}_s] \\ &= \mathbb{E}\left[\int_s^t \mathbb{E}[\beta_u | \mathcal{Y}_u] du | \mathcal{Y}_s\right] + \mathbb{E}[\mathbb{E}[m_t - m_s | \mathcal{F}_s] | \mathcal{Y}_s] \\ &= \mathbb{E}\left[\int_s^t \hat{\beta}_u du | \mathcal{Y}_s\right], \end{aligned}$$

because m is a $((\mathcal{F}_t), \mathbb{P})$ -martingale. Therefore, M is a locally square integrable $((\mathcal{Y}_t), \mathbb{P})$ -martingale. So, by Lemma 3, there is a (\mathcal{Y}_t) -adapted process Γ such that \mathbb{P} almost surely

$$M_t = \int_0^t \Gamma_s d\nu_s, \quad t \in [0, T],$$

and we can write

$$(44) \quad \hat{\zeta}_t = \hat{\zeta}_0 + \int_0^t \hat{\beta}_s ds + \int_0^t \Gamma_s d\nu_s, \quad t \in [0, T].$$

Now we wish to identify the process Γ . As in the proof of Theorem 8.11 in [8] we shall do it by using the unique decomposition of special semimartingales. From the representation (38) of the process Z^* defined by (35), applying the differentiation rule we get

$$\begin{aligned} \zeta_t Z_t^* &= \int_0^t \zeta_s [q_s(X) d \langle N^* \rangle_s + dN_s^*] + \int_0^t Z_s^* [\beta_s ds + dm_s] \\ &+ \int_0^t \lambda_s d \langle N^* \rangle_s, \quad t \in [0, T]. \end{aligned}$$

Proceeding as in [8], one can then derive a decomposition of $\hat{\zeta}Z^*$ as a special semimartingale with respect to (\mathcal{Y}_t) where the bounded variation term is

$$(45) \quad \int_0^t [\zeta_s \widehat{q_s(X)} + \hat{\lambda}_s] d \langle N^* \rangle_s + \int_0^t Z_s^* \hat{\beta}_s ds, \quad t \in [0, T].$$

However, using (40) and (44), applying the differentiation rule we obtain another decomposition of $\hat{\zeta}Z^*$ as a special semimartingale with respect to (\mathcal{Y}_t) where the bounded variation term is

$$(46) \quad \int_0^t [\hat{\zeta}_s \pi_s(q) + \Gamma_s] d \langle N^* \rangle_s + \int_0^t Z_s^* \hat{\beta}_s ds, \quad t \in [0, T].$$

Since the canonical decomposition of the special semimartingale $\hat{\zeta}Z^*$ is unique, in particular the integrals in (45) and (46) must be almost surely equal. This gives that $\langle N^* \rangle \otimes \mathbb{P}$ almost everywhere in $[0, T] \times \Omega$ the following holds :

$$\Gamma_s = \hat{\lambda}_s + \zeta_s \widehat{q_s(X)} - \hat{\zeta}_s \pi_s(q).$$

Hence, inserting into (44), the representation (43) follows. ■

Now we may extend partly Zakai's approach (see e.g. [29, 8]) to derive equations for the optimal filter when the signal X is a diffusion process.

5 Optimal filtering of a diffusion process in fractional Brownian observation noise

Here we assume that the signal process X satisfies the stochastic differential equation

$$(47) \quad X_t = \eta + \int_0^t a(s, X_s) ds + \int_0^t b(s, X_s) dV_s^{1/2}, \quad t \in [0, T],$$

where with respect to \mathbb{P} (or $\tilde{\mathbb{P}}$) the process $V^{1/2} = (V_t^{1/2}, t \in [0, T])$ is a standard Brownian motion independent of W such that the pair (η, ξ) is independent of $(V^{1/2}, W)$. Of course we suppose that the distribution $\mu_{(X, \xi)}$ is uniquely well-defined. Moreover we assume that the conditional distribution of η given ξ is some fixed π_0 .

Let ϕ be any smooth function with regular first and second order derivatives ϕ' and ϕ'' respectively. Then, according to Itô's formula, the process $(\phi(X_t), t \in [0, T])$ is a semimartingale with the following decomposition :

$$\phi(X_t) = \phi(\eta) + \int_0^t \mathcal{L}_s \phi(X_s) ds + \int_0^t \phi'(X_s) b(s, X_s) dV_s^{1/2}, \quad t \in [0, T],$$

where, for $s \in [0, T]$, \mathcal{L}_s is the second order differential operator defined by

$$\mathcal{L}_s \phi(x) = a(s, x) \phi'(x) + \frac{1}{2} b^2(s, x) \phi''(x), \quad x \in \mathbb{R}.$$

Hence a straightforward application of Proposition 2 gives an equation for the optimal filter π_t : for all $t \in [0, T]$,

$$(48) \quad \pi_t(\phi) = \pi_0(\phi) + \int_0^t \pi_s(\mathcal{L}_s \phi) ds + \int_0^t [\pi_s(\phi q) - \pi_s(\phi) \pi_s(q)] d\nu_s,$$

where $\pi_s(\phi q) = \mathbb{E}[\phi(X_s) q_s(X) | \mathcal{Y}_s]$.

In order to be able to derive an analogue of Zakai's formula for the unnormalized filter σ_t , now we deal with the local density process Λ in the Girsanov type formula of Proposition 1. Recall that

$$\Lambda_t = \exp(\tilde{N}_t - \frac{1}{2} \langle \tilde{N} \rangle_t).$$

Taking into account equation (22), this definition can be rewritten in terms of the processes Z and $\langle N \rangle$, defined by (34) and (29) respectively, as

$$\Lambda_t = \exp(Z_t - \frac{1}{2} \langle N \rangle_t).$$

But from the representations (33) and (39) of $\langle N \rangle$ and Z this can also be written as

$$\Lambda_t = \exp \left(\int_0^t q_s(X) dZ_s^* - \frac{1}{2} \int_0^t q_s^2(X) d \langle N^* \rangle_s \right).$$

Hence Λ appears as the solution of the stochastic differential equation

$$(49) \quad \Lambda_t = 1 + \int_0^t q_s(X) \Lambda_s dZ_s^*, \quad t \in [0, T].$$

Recall that by definition of the unnormalized filter σ_t

$$\sigma_t(\phi) = \tilde{\mathbb{E}}[\phi(X_t) \Lambda_t | \mathcal{Y}_t],$$

and in particular

$$(50) \quad \tilde{\Lambda}_t \triangleq \sigma_t(1) = \tilde{\mathbb{E}}[\Lambda_t | \mathcal{Y}_t].$$

Now we obtain a formula for the process $\tilde{\Lambda} = (\tilde{\Lambda}_t, t \in [0, T])$:

Proposition 3 *The process $\tilde{\Lambda}$ defined by (50) is given \mathbb{P} almost surely by*

$$(51) \quad \tilde{\Lambda}_t = \exp \left\{ \int_0^t \pi_s(q) dZ_s^* - \frac{1}{2} \int_0^t \pi_s^2(q) d \langle N^* \rangle_s \right\}, \quad t \in [0, T],$$

where Z^* is defined by (35) and $\pi_s(q)$ is the conditional expectation $\pi_s(q) = \mathbb{E}[q_s(X) | \mathcal{Y}_s]$ with respect to \mathbb{P} .

Proof The proof parallels that of Theorem 18.21 in [8]. Recall that Λ is a $((\mathcal{F}_t), \tilde{\mathbb{P}})$ -martingale. Of course, consequently $\tilde{\Lambda}$ is a $((\mathcal{Y}_t), \tilde{\mathbb{P}})$ -martingale. Under $\tilde{\mathbb{P}}$, the process Z^* which can be written as

$$Z_t^* = \int_0^t k_*^t(s) d\tilde{W}_s, \quad t \in [0, T],$$

is a continuous Gaussian (\mathcal{Y}_t) -martingale such that $\langle Z^* \rangle = \langle N^* \rangle$. Hence there exists a (\mathcal{Y}_t) -adapted process g such that $\tilde{\mathbb{P}}$ almost surely

$$(52) \quad \tilde{\Lambda}_t = 1 + \int_0^t g_s dZ_s^*, \quad t \in [0, T].$$

We shall identify g by using the unique decomposition of special semimartingales. Using the differentiation rule to compute ΛZ^* , from (49) and (38) we get

$$\begin{aligned} \Lambda_t Z_t^* &= \int_0^t \Lambda_s dZ_s^* + \int_0^t Z_s^* d\Lambda_s + \langle \Lambda, Z^* \rangle_t \\ &= \int_0^t \Lambda_s dZ_s^* + \int_0^t Z_s^* q_s(X) \Lambda_s dZ_s^* + \int_0^t q_s(X) \Lambda_s d\langle N^* \rangle_s. \end{aligned}$$

Proceeding as in the proof of Theorem 18.21 in [8] one can derive a decomposition of $\tilde{\Lambda} Z^*$ as a special $((\mathcal{Y}_t), \tilde{\mathbb{P}})$ -semimartingale where the bounded variation term is

$$\int_0^t \Lambda_s \widetilde{q}_s(X) d\langle N^* \rangle_s, \quad t \in [0, T],$$

where $\Lambda_s \widetilde{q}_s(X) = \tilde{\mathbb{E}}[\Lambda_s q_s(X) \mid \mathcal{Y}_s]$.

However, using (52) and (40), again applying the differentiation rule we can obtain another decomposition of $\tilde{\Lambda} Z^*$ as a special $((\mathcal{Y}_t), \tilde{\mathbb{P}})$ -semimartingale where the bounded variation term is

$$\int_0^t g_s d\langle N^* \rangle_s, \quad t \in [0, T].$$

By the uniqueness of the decomposition of a special semimartingale we obtain that $\langle N^* \rangle \otimes \tilde{\mathbb{P}}$ almost everywhere in $[0, T] \times \Omega$

$$\begin{aligned} g_s &= \Lambda_s \widetilde{q}_s(X) \\ &= \tilde{\mathbb{E}}[\Lambda_s q_s(X) \mid \mathcal{Y}_s]. \end{aligned}$$

However, from (28) and (50), this means that $\langle N^* \rangle \otimes \tilde{\mathbb{P}}$ almost everywhere in $[0, T] \times \Omega$

$$g_s = \tilde{\Lambda}_s \pi_s(q).$$

Substituting in (52), we obtain the equation

$$(53) \quad \tilde{\Lambda}_t = 1 + \int_0^t \tilde{\Lambda}_s \pi_s(q) dZ_s^*, \quad t \in [0, T],$$

which has, with respect to $\tilde{\mathbb{P}}$ the unique solution

$$\tilde{\Lambda}_t = \exp \left\{ \int_0^t \pi_s(q) dZ_s^* - \frac{1}{2} \int_0^t \pi_s^2(q) d \langle N^* \rangle_s \right\}, \quad t \in [0, T].$$

Hence, since \mathbb{P} is equivalent to $\tilde{\mathbb{P}}$, the proposition is proved. \blacksquare

Now we obtain an analogue of classical Zakai's equation (see e.g. [29, 8]) for the unnormalized filter σ_t :

Proposition 4 *Let σ_t be the unnormalized filter in the signal-observation model defined by equations (47) and (1). Then for any smooth function ϕ the following equation holds :*

$$(54) \quad \sigma_t(\phi) = \sigma_0(\phi) + \int_0^t \sigma_s(\mathcal{L}_s \phi) ds + \int_0^t \sigma_s(\phi q) dZ_s^*, \quad t \in [0, T],$$

where the process Z^* is given by (35) and $\sigma_0(\phi) = \pi_0(\phi)$.

Proof We observe that from its definition we have

$$(55) \quad \sigma_t(\phi) = \tilde{\Lambda}_t \pi_t(\phi).$$

But, from equations (48), (53) and (40) we have

$$\pi_t(\phi) = \pi_0(\phi) + \int_0^t \pi_s(\mathcal{L}_s \phi) ds + \int_0^t [\pi_s(\phi q) - \pi_s(\phi) \pi_s(q)] d\nu_s, \quad t \in [0, T],$$

and

$$\tilde{\Lambda}_t = 1 + \int_0^t \tilde{\Lambda}_s \pi_s^2(q) d \langle N^* \rangle_s + \int_0^t \tilde{\Lambda}_s \pi_s(q) d\nu_s, \quad t \in [0, T].$$

Then, applying Itô's formula, we get

$$d\sigma_t(\phi) = \tilde{\Lambda}_t d\pi_t(\phi) + \pi_t(\phi) d\tilde{\Lambda}_t + d \langle \tilde{\Lambda}, \pi(\phi) \rangle_t$$

$$\begin{aligned}
&= \tilde{\Lambda}_t \pi_t(\mathcal{L}_t \phi) dt + \tilde{\Lambda}_t [\pi_t(\phi q) - \pi_t(\phi) \pi_t(q)] d\nu_t \\
&+ \pi_t(\phi) \tilde{\Lambda}_t \pi_t(q) d\nu_t + \pi_t(\phi) \tilde{\Lambda}_t \pi_t^2(q) d \langle N^* \rangle_t \\
&+ \tilde{\Lambda}_t \pi_t(q) [\pi_t(\phi q) - \pi_t(\phi) \pi_t(q)] d \langle N^* \rangle_t \\
&= \tilde{\Lambda}_t \pi_t(\mathcal{L}_t \phi) dt + \tilde{\Lambda}_t \pi_t(\phi q) [d\nu_t + \pi_t(q) d \langle N^* \rangle_t].
\end{aligned}$$

Again, using (55) and (40), the equation can be rewritten as

$$d\sigma_t(\phi) = \sigma_t(\mathcal{L}_t \phi) dt + \sigma_t(\phi q) dZ_t^*,$$

which gives nothing but (54). ■

Actually, from Propositions 3 and 4, it appears that to give a complete solution to the filtering problem we need also an equation for the conditional expectation $\pi_t(\psi)$ of a functional $\psi(X^{(t)})$ of the state process, if only for $\pi_t(q)$. In the next section we investigate this question in the case of linear systems for which we show that closed form equations can be derived for the optimal filter.

6 Optimal filtering in conditionally Gaussian linear systems with fractional Brownian observation noise

Let us deal here with the particular situation where *the dynamics of the process* (X, Y) *is linear*. Precisely we suppose that, written in differential notation, under \mathbb{P} it is given by

$$(56) \quad \begin{cases} dX_t &= a(t)X_t dt + b(t)dV_t^{1/2}, \quad t \in [0, T], \quad X_0 = \eta, \\ dY_t &= A(t)X_t dt + B(t)dW_t, \quad t \in [0, T], \quad Y_0 = \xi. \end{cases}$$

We assume that the random initial conditions η and ξ in (1) are such that the pair (η, ξ) is independent of $(V^{1/2}, W)$ where $V^{1/2}$ and W are independent Brownian motion and fBm with Hurst parameter H respectively. The conditional distribution π_0 is assumed to be Gaussian with mean $\hat{\eta}_0 = \hat{\eta}_0(\xi)$ and

variance $\gamma_0 = \gamma_0(\xi)$ which is supposed almost surely positive. Clearly, under these assumptions, the distribution of process (X, Y) is uniquely well-defined and enters into the general framework described above. Moreover it is obvious that the pair (X, Y) is conditionally Gaussian i.e. for all $t \in [0, T]$, $n = 1, 2, \dots$ and $t_1, t_2, \dots, t_n \in [0, t]$ the joint conditional distribution of $(X_{t_1}, X_{t_2}, \dots, X_{t_n})$ given \mathcal{Y}_t is Gaussian.

Notice that here, for a continuous function $x = (x_t, t \in [0, T])$, according to definition (15), we have $C(x)(t) = C(t)x(t)$ where $C(t) = B^{-1}(t)A(t)$ for all $t \in [0, T]$. Hence, since moreover the functional $C \rightarrow (q_{t_1}^C, q_{t_2}^C, \dots, q_{t_n}^C)$ defined from (12) and (10) is linear, the system $((X, q(X)), Y)$ is also conditionally Gaussian.

Then in particular for any $t \in [0, T]$ the optimal filter π_t is a Gaussian distribution and the filtering equations can be reduced to equations for its mean \hat{X}_t and for the conditional variance $\gamma(t)$ of the filtering error i.e.

$$(57) \quad \hat{X}_t \triangleq \mathbb{E}[X_t | \mathcal{Y}_t]; \quad \gamma(t) \triangleq \mathbb{E}[(X_t - \hat{X}_t)^2 | \mathcal{Y}_t], \quad t \in [0, T].$$

We shall show that here a closed form system of equations for \hat{X}_t and γ_t can be determined. We introduce the process $\gamma_{x,q}$ defined as

$$(58) \quad \gamma_{x,q}(t) \triangleq \mathbb{E}[(X_t - \hat{X}_t)(q_t(X) - \pi_t(q)) | \mathcal{Y}_t], \quad t \in [0, T].$$

Now we start with the following :

Lemma 4 *For all $t \in [0, T]$, the mean \hat{X}_t and the variance $\gamma(t)$ of the optimal filter π_t in model (56) satisfy the equations*

$$(59) \quad \hat{X}_t = \hat{\eta}_0 + \int_0^t a(s)\hat{X}_s ds + \int_0^t \gamma_{x,q}(s) d\nu_s,$$

and

$$(60) \quad \gamma(t) = \gamma_0 + \int_0^t 2a(s)\gamma(s)ds + \int_0^t b^2(s)ds - \int_0^t \gamma_{x,q}^2(s) d \langle N^* \rangle_s,$$

where $\gamma_{x,q}$ is the process given by (58).

Proof Applying Proposition 2 to the semimartingale X we obtain

$$\hat{X}_t = \hat{\eta}_0 + \int_0^t a(s) \hat{X}_s ds + \int_0^t [X_s \widehat{q}_s(X) - \widehat{X}_s \pi_s(q)] d\nu_s, \quad t \in [0, T].$$

Therefore equation (59) holds since the process appearing in the martingale part of the right hand side of this representation is nothing but $\gamma_{X,q}$ given by (58). Now applying Itô's formula, we get the following representation of the semimartingale \hat{X}^2 :

$$(61) \quad \begin{aligned} [\hat{X}_t]^2 &= [\hat{\eta}_0]^2 + \int_0^t 2a(s) [\hat{X}_s]^2 ds + \int_0^t \gamma_{X,q}^2(s) d \langle N^* \rangle_s \\ &\quad + \int_0^t 2\gamma_{X,q}(s) \hat{X}_s d\nu_s, \quad t \in [0, T]. \end{aligned}$$

On the other hand, applying Itô's formula to the semimartingale X^2 we get

$$X_t^2 = \eta^2 + \int_0^t 2a(s) X_s^2 ds + \int_0^t b^2(s) ds + \int_0^t 2b(s) X_s dV_s^{1/2}, \quad t \in [0, T].$$

Hence, again applying Proposition 2, we obtain

$$(62) \quad \begin{aligned} \widehat{X}_t^2 &= \widehat{\eta}_0^2 + \int_0^t 2a(s) \widehat{X}_s^2 ds + \int_0^t b^2(s) ds \\ &\quad + \int_0^t [X_s^2 \widehat{q}_s(X) - \widehat{X}_s^2 \pi_s(q)] d\nu_s, \quad t \in [0, T]. \end{aligned}$$

Subtracting equation (61) from equation (62) leads to

$$\begin{aligned} \gamma(t) &= \gamma_0 + \int_0^t 2a(s) \gamma(s) ds + \int_0^t b^2(s) ds - \int_0^t \gamma_{X,q}^2(s) d \langle N^* \rangle_s \\ &\quad + \int_0^t [X_s^2 \widehat{q}_s(X) - \widehat{X}_s^2 \pi_s(q) - 2\gamma_{X,q}(s) \hat{X}_s] d\nu_s, \quad t \in [0, T]. \end{aligned}$$

But, using the conditionally Gaussian property, it is readily seen that the process appearing as the integrand in the martingale part of the right hand side above is almost surely zero. Consequently the last equation is nothing but (60). ■

Remark 3 Let us emphasize that in the case when the observation noise is also a standard Brownian motion, i.e. $H = \frac{1}{2}$, then the previous optimal filtering equations reduce to the usual Kalman equations. Actually, taking into account Remarks 1(d) and 2(c), in this case we have

$$q_t(X) = C(t)X_t; \quad \pi_t(q) = C(t)\hat{X}_t; \quad \gamma_{X,q}(t) = C(t)\gamma(t), \quad t \in [0, T].$$

Hence from (40) we have also

$$d\nu_t = B^{-1}(t)dY_t - C(t)\hat{X}_t dt = B^{-1}(t)[dY_t - A(t)\hat{X}_t dt].$$

Then equations (59)-(60) in Lemma 4 become

$$\hat{X}_t = \hat{\eta}_0 + \int_0^t a(s)\hat{X}_s ds + \int_0^t \frac{A(s)}{B^2(s)}\gamma(s)[dY_s - A(s)\hat{X}_s ds], \quad t \in [0, T],$$

$$\gamma(t) = \gamma_0 + \int_0^t 2a(s)\gamma(s)ds + \int_0^t b^2(s)ds - \int_0^t \frac{A^2(s)}{B^2(s)}\gamma^2(s)ds, \quad t \in [0, T],$$

which are nothing but the classical Kalman filter equations for a linear system driven by Brownian noises (see e.g. [17]).

Actually Lemma 4 permits to give an explicit solution of the filtering problem in the specific case of a noise free state equation when actually *the signal is a fixed random variable* i.e. in (56) the functions a and b are identically zero and hence $X_t \equiv \eta$. This means that the observation process is Y where

$$Y_t = \xi + \int_0^t A(s)\eta ds + \int_0^t B(s)dW_s, \quad t \in [0, T].$$

We shall use the notation $\hat{\eta}_t = \mathbb{E}[\eta | \mathcal{Y}_t]$ and then $\gamma(t) = \mathbb{E}[(\eta - \hat{\eta}_t)^2 | \mathcal{Y}_t]$. Here of course the process $q(X)$ defined by (32) and the corresponding conditional expectation $\pi_t(q)$ reduce to

$$q_t(X) = q_t^C \eta; \quad \pi_t(q) = q_t^C \hat{\eta}_t, \quad t \in [0, T],$$

where q^C is given by (12). Hence also

$$\gamma_{X,q}(t) = q_t^C \gamma(t), \quad t \in [0, T],$$

and equation (60) becomes

$$\gamma(t) = \gamma_0 - \int_0^t \gamma^2(s) [q_s^C]^2 d \langle N^* \rangle_s, \quad t \in [0, T].$$

This equation has an explicit solution

$$\gamma(t) = \left(\gamma_0^{-1} + \int_0^t [q_s^C]^2 d \langle N^* \rangle_s \right)^{-1}, \quad t \in [0, T].$$

Observe that from (6) and (11) it can be rewritten as

$$\gamma(t) = \left(\gamma_0^{-1} + \int_0^t k_C^t(s) C(s) ds \right)^{-1}, \quad t \in [0, T].$$

Moreover equation (59) reduces to

$$\hat{\eta}_t = \hat{\eta}_0 + \int_0^t q_s^C \gamma(s) d\nu_s, \quad t \in [0, T],$$

i.e., taking into account the representation (40) of the innovation process ν ,

$$\hat{\eta}_t = \hat{\eta}_0 + \int_0^t q_s^C \gamma(s) [dZ_s^* - q_s^C \hat{\eta}_s d \langle N^* \rangle_s], \quad t \in [0, T].$$

Then the conditional mean $\hat{\eta}_t$ can be obtained computing

$$\begin{aligned} d[\gamma_t^{-1} \hat{\eta}_t] &= \hat{\eta}_t d\gamma^{-1}(t) + \gamma^{-1}(t) d\hat{\eta}_t \\ &= \hat{\eta}_t [q_t^C]^2 d \langle N^* \rangle_t + \gamma^{-1}(t) \gamma(t) q_t^C [dZ_t^* - q_t^C \hat{\eta}_t d \langle N^* \rangle_t] \\ &= q_t^C dZ_t^*. \end{aligned}$$

This gives

$$\begin{aligned} \gamma_t^{-1} \hat{\eta}_t &= \gamma_0^{-1} \hat{\eta}_0 + \int_0^t q_s^C dZ_s^* \\ &= \gamma_0^{-1} \hat{\eta}_0 + \int_0^t k_C^t(s) B^{-1}(s) dY_s, \quad t \text{ in } [0, T], \end{aligned}$$

where the last equality can be easily checked from (38) and $dY_s = A(s)\eta ds + B(s)dW_s$.

Finally, this leads to

$$\hat{\eta}_t = \gamma(t) \left(\gamma_0^{-1} \hat{\eta}_0 + \int_0^t k_C^t(s) B^{-1}(s) dY_s \right).$$

Of course it appears that $(\hat{\eta}_t, \gamma(t))$ is nothing but the solution of the filtering problem which was directly derived for this simple model in [16] (see also [15]). Observe also that this is an analogue for fBm observation noise of Theorem 12.2 in [17] for Brownian motion noise.

Example Let us consider the particular case where $A = B \equiv 1$ (and then also $C \equiv 1$) i.e. we deal with the model $Y_t = \xi + \eta t + W_t$, $t \in [0, T]$. Here we get

$$\hat{\eta}_t = \gamma_t \left\{ \gamma_0^{-1} \hat{\eta}_0 + \kappa_H^{-1} \int_0^t s^{\frac{1}{2}-H} (t-s)^{\frac{1}{2}-H} dY_s \right\},$$

and

$$\gamma(t) = \left\{ \gamma_0^{-1} + \lambda_H^{-1} t^{2-2H} \right\}^{-1}.$$

Now let us come back to the more general case of this section. We look for equations for the processes $\pi(q)$ and $\gamma_{X,q}$. We begin by establishing a representation of the process $q(X)$ as the solution of an Itô-Volterra type equation with deterministic coefficients.

Lemma 5 *Let the process $q(X) = (q_t(X), t \in [0, T])$ be defined by (31)-(32) with $C(x)(t) = C(t)x(t)$, $C(t) = B^{-1}(t)A(t)$, $t \in [0, T]$. Then $q(X)$ satisfies the following equation*

$$\begin{aligned} q_t(X) &= q^C(t, 0)\eta + \int_0^t a(u)q^C(t, u)X_u du \\ (63) \quad &+ \int_0^t b(u)q^C(t, u)dV_u^{1/2}, \quad t \in [0, T], \end{aligned}$$

where $q^C(\cdot, \cdot)$ permits the representation (14).

Proof Starting from (13) and the first equation in (56), for all $t \in [0, T]$ we can write

$$\begin{aligned} \int_0^t q_s(X) d \langle N^* \rangle_s &= \int_0^t k_*^t(s) C(s) X_s ds \\ &= \int_0^t k_*^t(s) C(s) \left\{ \eta + \int_0^s a(u) X_u du + \int_0^s b(u) dV_u^{1/2} \right\} ds \\ &= \left[\int_0^t k_*^t(s) C(s) ds \right] \eta + \int_0^t a(u) \left\{ \int_u^t k_*^t(s) C(s) ds \right\} X_u du \\ &\quad + \int_0^t b(u) \left\{ \int_u^t k_*^t(s) C(s) ds \right\} dV_u^{1/2}. \end{aligned}$$

Hence, taking into account representation (14), this can be rewritten as

$$\begin{aligned} \int_0^t q_s(X) d \langle N^* \rangle_s &= \left[\int_0^t q^C(s, 0) d \langle N^* \rangle_s \right] \eta \\ &\quad + \int_0^t a(u) \left\{ \int_u^t q^C(s, u) d \langle N^* \rangle_s \right\} X_u du \\ &\quad + \int_0^t b(u) \left\{ \int_u^t q^C(s, u) d \langle N^* \rangle_s \right\} dV_u^{1/2}. \end{aligned}$$

Finally we get

$$\begin{aligned} \int_0^t q_s(X) d \langle N^* \rangle_s &= \int_0^t q^C(s, 0) \eta d \langle N^* \rangle_s \\ &\quad + \int_0^t \left\{ \int_0^s a(u) q^C(s, u) X_u du \right\} d \langle N^* \rangle_s \\ &\quad + \int_0^t \left\{ \int_0^s b(u) q^C(s, u) dV_u^{1/2} \right\} d \langle N^* \rangle_s, \end{aligned}$$

which means nothing but that representation (63) holds. \blacksquare

Of course $q(X)$ is not a semimartingale and we can not directly apply Proposition 2 to obtain an equation for the process $\pi(q)$. To overcome this difficulty we shall use the technique which was proposed in [12, 13, 14] to transform the problem into a filtering problem concerning a semimartingale. Let us fix some $t \in [0, T]$ and define the process $q^t(X) = (q_s^t(X), s \in [0, t])$ by

$$\begin{aligned} q_s^t(X) &= q^C(t, 0) \eta + \int_0^s a(u) q^C(t, u) X_u du \\ (64) \quad &\quad + \int_0^s b(u) q^C(t, u) dV_u^{1/2}, \quad s \in [0, t]. \end{aligned}$$

Observe that it is a semimartingale and moreover, taking $s = t$ in (64), from (63) we get

$$(65) \quad q_t^t(X) = q_t(X).$$

We introduce the processes $\gamma_{X,q}(t, \cdot)$ and $\gamma_{q,q}(t, \cdot)$ by

$$(66) \quad \gamma_{X,q}(t, s) \triangleq \mathbb{E}[(X_s - \hat{X}_s)(q_s^t(X) - \pi_s(q^t)) \mid \mathcal{Y}_s], \quad 0 \leq s \leq t,$$

$$(67) \quad \gamma_{q,q}(t, s) \triangleq \mathbb{E}[(q_s^t(X) - \pi_s(q^t))(q_s(X) - \pi_s(q)) \mid \mathcal{Y}_s], \quad 0 \leq s \leq t.$$

Of course, taking $s = t$ in these definitions, it appears that $\gamma_{X,q}(t, t)$ is nothing but $\gamma_{X,q}(t)$ defined by (58) and $\gamma_{q,q}(t, t)$ is the conditional variance $\mathbb{E}[(q_t(X) - \pi_t(q))^2 | \mathcal{Y}_t]$.

Then we can state

Lemma 6 *Let the process $q^t(X)$ be defined by (64). Then the following representations of the conditional expectation $\pi_s(q^t) = \mathbb{E}[q_s^t(X) | \mathcal{Y}_s]$ and of the conditional covariances $\gamma_{X,q}(t, s)$ and $\gamma_{q,q}(t, s)$, defined by (66) and (67) respectively, hold for $0 \leq s \leq t$:*

$$(68) \quad \pi_s(q^t) = q^C(t, 0)\hat{\eta}_0 + \int_0^s a(u)q^C(t, u)\hat{X}_u du + \int_0^s \gamma_{q,q}(t, u)d\nu_u,$$

$$(69) \quad \begin{aligned} \gamma_{X,q}(t, s) &= q^C(t, 0)\gamma_0 + \int_0^s a(u)[q^C(t, u)\gamma(u) + \gamma_{X,q}(t, u)]du \\ &+ \int_0^s b^2(u)q^C(t, u)du - \int_0^s \gamma_{X,q}(u)\gamma_{q,q}(t, u)d \langle N^* \rangle_u, \end{aligned}$$

$$(70) \quad \begin{aligned} \gamma_{q,q}(t, s) &= q^C(t, 0)q^C(s, 0)\gamma_0 \\ &+ \int_0^s a(u)[q^C(t, u)\gamma_{X,q}(s, u) + q^C(s, u)\gamma_{X,q}(t, u)]du \\ &+ \int_0^s b^2(u)q^C(t, u)q^C(s, u)du - \int_0^s \gamma_{q,q}(t, u)\gamma_{q,q}(s, u)d \langle N^* \rangle_u. \end{aligned}$$

Proof Equation (68) is an immediate consequence of Proposition 2 applied to the semimartingale $q^t(X)$.

To get (69) we start from the first equation in (56) and equation (64) to write the semimartingale representation of $Xq^t(X)$ by using the differentiation rule:

$$\begin{aligned} X_s q_s^t(X) &= q^C(t, 0)\eta^2 + \int_0^s a(u)[q^C(t, u)X_u^2 + X_u q_u^t(X)]du \\ &+ \int_0^s b^2(u)q^C(t, u)du + \int_0^s b(u)[q^C(t, u)X_u + q_u^t(X)]dV_u^{1/2}. \end{aligned}$$

Hence, again applying Proposition 2, we get

$$(71) \quad \begin{aligned} X_s \widehat{q_s^t(X)} &= q^C(t, 0)\widehat{\eta^2_0} + \int_0^s a(u)[q^C(t, u)\widehat{X_u^2} + X_u \widehat{q_u^t(X)}]du \\ &+ \int_0^s b^2(u)q^C(t, u)du + \int_0^s [X_u \widehat{q_u^t(X)} q_u(X) - X_u \widehat{q_u^t(X)} \pi_u(q)]d\nu_u. \end{aligned}$$

Now, from (59) and (68), we get a representation of the semimartingale $\hat{X}\pi(q^t)$:

$$\begin{aligned}
\widehat{X}_s\pi_s(q^t) &= q^C(t, 0)[\widehat{\eta}_0]^2 + \int_0^s a(u)[q^C(t, u)\widehat{X}_u^2 + \widehat{X}_u\pi_u(q^t)]du \\
(72) \quad &+ \int_0^s \gamma_{X,q}(u)\gamma_{q,q}(t, u)d\langle N^* \rangle_u \\
&+ \int_0^s [\widehat{X}_u\gamma_{q,q}(t, u) + \gamma_{X,q}(t, u)\pi_u(q^t)]d\nu_u.
\end{aligned}$$

Subtracting (72) from equation (71) leads immediately to (69) since, from the conditionally Gaussian property, it appears that the martingale part of the obtained semimartingale is zero.

Equation (70) can be obtained, through developments quite parallel to those in the previous proofs, by computing $\pi_s(q^t q^r) - \pi_s(q^t)\pi_s(q^r)$ for $r, t \geq s$ and observing that, due to (65), $\gamma_{q,q}(t, s)$ is nothing but the value of this quantity for $r = s$. \blacksquare

Now, as an immediate consequence of Lemmas 4, 5 and 6, we may give the solution of the filtering problem in the linear system (56) :

Proposition 5 *Let (X, Y) the solution process of the linear system (56). Let $q(X) = (q_t(X), t \in [0, T])$ be the auxiliary process defined by (31)-(32) with $C(x)(t) = C(t)x(t)$, $C(t) = B^{-1}(t)A(t)$, $t \in [0, T]$. Let also $q^C(\cdot, \cdot)$ be the function permitting the representation (14). Then the mean \hat{X}_t and the variance $\gamma(t)$ of the optimal filter π_t of X satisfy the equations (59) and (60) where*

$$\begin{aligned}
\nu_t &= \int_0^t k_*^t(s)B^{-1}(s)dY_s - \int_0^t \pi_s(q)d\langle N^* \rangle_s, \quad t \in [0, T], \\
\pi_t(q) &= q^C(t, 0)\hat{\eta}_0 + \int_0^t a(u)q^C(t, u)\hat{X}_u du + \int_0^t \gamma_{q,q}(t, u)d\nu_u,
\end{aligned}$$

and processes $\gamma_{X,q}(\cdot, \cdot)$ and $\gamma_{q,q}(\cdot, \cdot)$ satisfy (69) and (70) respectively.

Remark 4 Let us mention that in the case when the noise in the state equation is also a fBm, developments similar to those above are still possible. In that case one may follow for the signal X the technique, which has been used above for $q(X)$, to transform the original problem into a filtering problem concerning a semimartingale. This will be reported in a forthcoming paper as well as extensions to nonlinear systems.
