## ON THE SIZE OF PROJECTIONS : II

(The case of a single functional dependency)

Erol GELENBE

Danièle GARDY

ABSTRACT : In this paper we consider tabulated data or relations in a data base system which are constrained by functional dependencies. This implies that the data in certain columns of each table is determined by the data contained in some other columns. The problem we address is that of the computation of the size of projections of the data on a subset of the columns. This may be viewed as the projection of data in some  $k$  dimensional space into a smaller subspace. We thus extend results we had previously obtained [1] for relations without functional dependencies to the case with functional dependencies.

RESUME : Nous nous intéressons au problème du calcul de la taille des projections de relations dans une base de données relationnelle. Les résultats que nous avons précédemment obtenu [1] pour le cas sans dépendances fonctionnelles sont rappelés : une nouvelle formule pour la taille moyenne d'une projection est donnée. Nous obtenons ensuite des formules pour la distribution et pour la taille moyenne de projections de relations en présence d'une dépendance fonctionnelle.

On the size of projections : II

(The case with simple systems of functional dependencies)

1. Introduction

Consider  $\tau_k$  the  $k$ -dimensional space of vectors of the form

$$t = (t_1, \dots, t_k)$$

where each  $t_i$  takes its values in a finite set  $D_i$ . Thus  $\tau_k = D_1 \times D_2 \times \dots \times D_k$ . We shall be interested in subsets of  $\tau_k$  which may be viewed as *tables* of data points or as *relations* in a relational data base system. Let such a subset be

$$T_{lk} \subset \tau_k$$

where  $|T_{lk}| = l$  (i.e.  $T_{lk}$  contains  $l$  vectors of  $\tau_k$ ).

We will examine *projections* of  $T_{lk}$  into subspaces of  $\tau_k$ .

The projection  $\pi_{j_1 \dots j_u}$  of a vector  $t \in \tau_k$  is the  $u$ -dimensional vector

$$\pi_{j_1 \dots j_u}(t) = (t_{j_1}, \dots, t_{j_u})$$

where  $j_i \in (1, \dots, k)$ . Similarly, we define the projection of the table or relation  $T_{lk}$  as

$$\pi_{j_1 \dots j_u}(T_{lk}) = \{ \pi_{j_1 \dots j_u}(t) : t \in T_{lk} \}$$

As in a previous paper [1], we are interested in the *size of projections*. There are several reasons which motivate this interest

Several operations of interest in data base systems often contain the computation of projections as one of their components. The time necessary for the execution of such operations will thus be determined in part by the size of the projections obtained [2,3]. In another application area, related to data analysis (statistical data, physics experiments, etc.) projections of the initial data are obtained in order to examine properties of interest. In other cases, if a graphics output is used, projections of the data into two or three dimensions will often be used in order to obtain a visually meaningful presentation. In all of these cases, the number of data points contained in the projection will have an important influence on the storage necessary or on the run time of the processing algorithms used.

Often the information contained in each of the columns of a given table or relation  $T_{lk}$  will not be independent. One type of restriction common to data bases are the well known *functional dependencies*.

A *functional dependency* will be denoted by

$$x \rightarrow y \quad \text{or} \quad f(x,y)$$

and expressed by "x implies y" where x and y are subvectors of the vector t :

$$x = (t_{x_1}, \dots, t_{x_X}), \quad t_{x_i} \in \{t_1, \dots, t_k\}$$

$$y = (t_{y_1}, \dots, t_{y_Y}), \quad t_{y_j} \in \{t_1, \dots, t_k\}$$

We shall say that  $T_{lk}$  satisfies  $x \rightarrow y$  if and only if for all  $t, t' \in T_{lk}$ ,

$$\pi_{x_1, \dots, x_X}(t) = \pi_{x_1, \dots, x_X}(t')$$

$$\Rightarrow \pi_{y_1, \dots, y_Y}(t) = \pi_{y_1, \dots, y_Y}(t')$$

A typical example would be the case of the data base of a government organisation's employees in which the rank and seniority would completely determine the salary : (RANK, SENIORITY)  $\rightarrow$  (SALARY).

In the general case we can assume that  $T_{\ell k}$  satisfies a family  $F$  of functional dependencies

$$F = \{f(x,y) : x,y \text{ subvectors of } t\} .$$

The problem we shall address in this paper is the following.

\* Suppose that data tables of the form  $T_{\ell k}$  are generated in some "random" manner. Then what is the probability distribution of the size of the projection  $\pi_{j_1, \dots, j_n}(T_{\ell k})$  given that  $\ell$  (the size of the table  $T_{\ell k}$ ) is known ?

In [1] we solved this problem in the absence of functional dependencies, and we provided an efficient computational algorithm to obtain this probability distribution. The assumption made was that the tables  $T_{\ell k}$  are generated at random with a uniform distribution.

Here we shall make similar assumption but consider the case where functional dependencies hold.

In section 2 we shall recall the main result obtained in [1] ; we shall also give a new result providing a closed form expression for the *average size* of a projection in the absence of functional dependencies.

In section 3 we shall consider the simplest case of a single functional dependency. It will be analysed both for uniform and non-uniform distributions of attribute values on the domains. Again, formulae for the average size of the projection will be given together with the probability distribution.

2. Results obtained for a system without functional dependencies

In a previous paper [1] we had derived the probability distribution of the size of

$$\Pi_{j_1, \dots, j_u} (T_{\ell k})$$

which is the projection of the relation  $T_{\ell k}$  on coordinates  $(j_1, \dots, j_u)$ . We had also provided an efficient computational algorithm allowing us to compute any particular value of this distribution in time  $\ell^3$ .

The basic assumption concerning this "probabilistic" analysis was that any  $T_{\ell k}$  in  $\tau_k$  is generated at random by choosing any  $\ell$  distinct vectors  $(t_1, \dots, t_k)$  among the  $d = d_1 \dots d_k$  possibilities<sup>1)</sup> with equal probability. Furthermore it was assumed that any one of the coordinates  $t_i$  is uniformly distributed over  $D_i$ , and that the coordinates are independent.

In this section we shall conserve the same assumptions. We first recall the main result in [1], and then provide a new formula for the average size of projections.

Throughout this section we assume that all of the elements of any given domain  $D_i$  are equally likely to occur in any tuple  $t$  of a relation (uniform distribution assumption). We also assume that no functional dependency constrains the relations.

Let the probability and average value be denoted by :

$$P_{\ell, k}^{j_1, \dots, j_u}(r) = P[\text{size} (\Pi_{j_1 \dots j_u} (T_{\ell k})) = r ]$$

$$E_{\ell, k}^{j_1, \dots, j_u} = E[\text{size} (\Pi_{j_1 \dots j_u} (T_{\ell k}))]$$

Then we have the following result proved in [1] :

---

1)  $d_i = |D_i|$ , i.e. the size of the domain  $D_i$ .

RESULT 1.

$$P_{\ell,k}^{j_1 \dots j_u(r)} = \frac{\binom{d j_1 \dots d j_u}{r}}{\binom{d}{\ell}} X_{r, \ell-r} (d/d j_1 \dots d j_u)$$

where we define

$$X_{a,b}(v) = \sum_{\substack{n_1, \dots, n_a \geq 0 \\ n_1 + \dots + n_a = b}} \prod_{m=1}^a \binom{v}{n_m+1}$$

The following formula is new. It provides an efficient tool for computing the average size of a projection.

RESULT 2. Let  $\delta = d_{j_1} \dots d_{j_u}$ ,  $\delta' = d/\delta$ . Then

$$E_{\ell,k}^{j_1 \dots j_u} = \delta \left[ 1 - \frac{\binom{d-\delta'}{\ell}}{\binom{d}{\ell}} \right]$$

$$\approx \ell \left[ 1 - \frac{1}{2\delta} (\ell-1) \right] \quad \text{for } \ell \ll \delta \ll d$$

Proof :

$$\begin{aligned} E_{\ell,k}^{j_1 \dots j_u} &= \sum_{r=1}^{\ell} r \cdot P_{\ell,k}^{j_1 \dots j_u(r)} \\ &= \sum_{r=1}^{\ell} r \frac{\binom{\delta}{r}}{\binom{d}{\ell}} X_{r, \ell-r}(\delta') \\ &= \frac{\delta}{\binom{d}{\ell}} \sum_{r=1}^{\ell} \binom{\delta-1}{r-1} X_{r, \ell-r}(\delta') \end{aligned}$$

$$X_{1, \ell-1}(\delta') = \binom{\delta'}{\ell}$$

$$\text{for } r > 1 : X_{r, \ell-r}(\delta') = \sum_{z=0}^{\ell-r} \binom{\delta'}{z+1} X_{r-1, \ell-r-z}(\delta')$$

Hence :

$$\begin{aligned} E_{\ell,k}^{j_1 \cdots j_u} &= \frac{\delta}{\binom{d}{\ell}} \left[ \binom{\delta'}{\ell} + \sum_{\substack{2 \leq r \leq \ell \\ 0 \leq z \leq \ell-r}} \binom{\delta-1}{r-1} \binom{\delta'}{z+1} X_{r-1, \ell-r-z}^{(\delta')} \right] \\ &= \frac{\delta'}{\binom{d}{\ell}} \left[ \binom{\delta'}{\ell} + \sum_{z=0}^{\ell-2} \binom{\delta'}{z+1} \sum_{s=1}^{\ell-z-1} \binom{\delta-1}{s} X_{s, \ell-z-1-s}^{(\delta')} \right] \end{aligned}$$

By noting that :

$$\sum_{s=1}^{\ell} p_{\ell,k}^{j_1 \cdots j_u}(s) = 1$$

We obtain :

$$\sum_{s=1}^{\ell-z-1} \binom{\delta-1}{s} X_{s, \ell-z-1-s}^{(\delta')} = \binom{\delta'(\delta-1)}{\ell-z-1}$$

Then :

$$\begin{aligned} E_{\ell,k}^{j_1 \cdots j_u} &= \frac{\delta}{\binom{d}{\ell}} \left[ \binom{\delta'}{\ell} + \sum_{z=0}^{\ell-2} \binom{\delta'}{z+1} \binom{d-\delta'}{\ell-z-1} \right] \\ &= \frac{\delta}{\binom{d}{\ell}} \cdot \sum_{z=1}^{\ell} \binom{\delta'}{z} \binom{d-\delta'}{\ell-z} \end{aligned}$$

Now, by applying the binomial formula to  $(1+X)^d$  written as  $(1+X)^{\delta'} \cdot (1+X)^{d-\delta'}$ , we obtain for  $0 \leq \ell \leq d$  :

$$\sum_{\substack{0 \leq s \leq \delta' \\ 0 \leq r \leq d-\delta' \\ s+r=\ell}} \binom{\delta'}{s} \binom{d-\delta'}{r} = \binom{\delta}{\ell}$$

For  $\delta' \geq \ell$ , we can write it as :

$$\binom{d}{\ell} = \sum_{s=0}^{\ell} \binom{\delta'}{s} \binom{d-\delta'}{\ell-s}$$

Hence the result :

$$E_{\ell, k}^{j_1 \dots j_u} = \frac{\delta}{\binom{d}{\ell}} \left[ \binom{d}{\ell} - \binom{d-\delta'}{\ell} \right]$$

The proof of the approximate formula is then obtained as follows.

Clearly

$$\begin{aligned} \binom{d-\delta'}{\ell} \binom{d}{\ell} &= \frac{(d-\delta'-\ell+1) \dots (d-\delta')}{(d-\ell+1) \dots d} \\ &= \left(1 - \frac{\delta'}{d}\right)^\ell \frac{\left(1 - \frac{1}{d-\delta'}\right) \dots \left(1 - \frac{\ell-1}{d-\delta'}\right)}{\left(1 - \frac{1}{d}\right) \dots \left(1 - \frac{\ell-1}{d}\right)} \\ &\approx \left(1 - \frac{\ell}{\delta} + \frac{\ell(\ell-1)}{2\delta^2}\right) \left(1 - \frac{\ell(\ell-1)}{2(d-\delta')}\right) \left(1 + \frac{\ell(\ell-1)}{2d}\right) \\ &\approx \left(1 - \frac{\ell}{\delta} + \frac{\ell(\ell-1)}{2\delta^2}\right) \left(1 - \frac{\ell(\ell-1)}{2d}\right) \left(1 + \frac{1}{\delta}\right) \left(1 + \frac{\ell(\ell-1)}{2d}\right) \\ &\approx \left(1 - \frac{\ell}{\delta} + \frac{\ell(\ell-1)}{2\delta^2}\right) \left(1 - \frac{\ell(\ell-1)}{2d\delta}\right) \end{aligned}$$

where we have used the assumption  $\ell \ll \delta \ll d$ . The approximate formula then follows directly.

### 3. The case of a single functional dependency

In this section we shall consider a relation  $T_{\ell k}$  satisfying a single functional dependency  $x \rightarrow y$ . Without loss of generality we assume that  $x$  and  $y$  are disjoint. We shall examine both the case of uniform and non-uniform distributions of the values of the attributes on the domains.

The problem of computing the size of the projection  $\Pi_{xy}(T_{\ell k})$  on the set of columns  $(x,y)$  is identical to the case without functional dependencies ; this is in fact the case for any projection of the form  $\Pi_{xyz}(T_{\ell k})$ .

Thus in this section we shall concentrate on the size of  $\Pi_y(\Pi_{xy}(T_{\ell k}))$ . Using the formula for conditional probabilities we have

$$\begin{aligned} P[|\Pi_y(\Pi_{xy}(T_{\ell k}))| = r] \\ = P[|\Pi_y(\Pi_{xy}(T_{\ell k}))| = r \mid |\Pi_{xy}(T_{\ell k})| = j] \cdot P[|\Pi_{xy}(T_{\ell k})| = j] \end{aligned}$$

where the second term on the right hand side is available from RESULT 1. Thus it suffices to compute the conditional probability. The formulae derived in this section provide this conditional probability in the case of uniform and non-uniform distributions of attribute values over the domains.

Indeed, we notice that if  $T_{\ell k}$  satisfies  $x \rightarrow y$ , then the size of  $\Pi_{xy}(T_{\ell k})$  is the same as that of  $\Pi_x(T_{\ell k})$ . Therefore it suffices to replace  $|\Pi_{xy}(T_{\ell k})| = j$  by  $|\Pi_x(T_{\ell k})| = j$  in the above formula. The probability

$$P[|\Pi_x(T_{\ell k})| = j]$$

is then simply computed by setting  $x = (t_{j_1}, \dots, t_{j_u})$ ,  $r=j$ , in RESULT 1.

### 3.1. Uniform distributions

In this section we assume that all attribute values are equally likely (uniform distributions).

RESULT 3. The number of distinct tables of size  $m$  on columns  $(t_i, t_j)$  satisfying  $t_i \rightarrow t_j$ , whose projection on the  $j$ -th is of size  $n$  is

$$\alpha_{mn}^{ij} = \binom{d_j}{n} \binom{d_i}{m} \sum_{\substack{m_1, \dots, m_n \geq 1 \\ \sum_1^n m_i = n}} \frac{m!}{m_1! \dots m_n!}$$

Proof : There are  $\binom{d_j}{n}$  possible choices of the column on  $(t_j)$ . Once this is done we can choose any  $m$  distinct elements among the  $d_i$  : the number of distinct choices is  $\binom{d_i}{m}$ . We will then have to associate  $m_1 \geq 1$  of these to the first element of the  $(t_j)$  column,  $\dots, m_n \geq 1$  to the  $n$ -th element of the  $(t_j)$  column. Clearly we must have  $m_1 + \dots + m_n = m$ , and the number of distinct possibilities is simply for a fixed choice of  $m_1, \dots, m_n$  :

$$\binom{m}{m_1} \binom{m - m_1}{m_2} \dots \binom{m - \dots - m_{n-1}}{m_n} = \frac{m!}{m_1! \dots m_n!}$$

hence the result.

COROLLARY 4. Let  $x, y$  be subvectors of  $t$  such that  $x \cup y = t, x \cap y = \emptyset$ .

Let  $T_{\ell k}$  be a relation (on  $t$ ) satisfying  $x \rightarrow y$ . Assuming that, for a given  $\ell$ , all the  $T_{\ell k}$  are equally likely to occur, the probability that  $\Pi_y(T_{\ell k})$  is of size  $r$  is :

$$P_{\ell, k}^y(r) = \frac{\binom{d_y}{r}}{(d_y)^\ell} \sum_{\substack{m_1, \dots, m_r \geq 1 \\ \sum_1^r m_i = \ell}} \frac{\ell!}{m_1! \dots m_r!}$$

(where  $d_y = \prod_{t_i \in y} d_i, d_x = \prod_{t_i \in x} d_i$ )

Proof : This is in fact a consequence of RESULT 3 since there are

$$\binom{d_x}{\ell} (d_y)^\ell$$

distinct such tables  $T_{\ell k}$ . Therefore

$$P_{\ell, k}^y(r) = \frac{\alpha_{\ell k}^{xy}}{\binom{d_x}{\ell} (d_y)^\ell}$$

RESULT 5.  $E_{\ell k}^y$  the average size of  $\Pi_y(T_{\ell k})$  if  $x \cup y = t$ ,  $x \cap y = \emptyset$ , and  $T_{\ell k}$  is a relation on  $t$ , is

$$E_{\ell k}^y = d_y \left[ 1 - \left( \frac{d_y - 1}{d_y} \right)^\ell \right]$$

$$\approx \ell - \frac{\ell^2}{2} \frac{1}{d_y} \quad \text{for } \ell \ll d_y$$

so that the relative reduction in size is, on the average,

$$\frac{1}{\ell}(\ell - E_{\ell k}^y) \approx \frac{\ell}{2} \cdot \frac{1}{d_y} \quad \text{for } \ell \ll d_y$$

Proof : This formula can be derived somewhat laboriously directly from COROLLARY 4 : in fact this is exactly how we have initially discovered it. We shall give a simple indirect proof, however. Let  $D_y$  denote the domain of  $y$ , and let  $e_y$  be any one of its elements. Clearly we may write

$$E_{\ell, k}^y = \sum_{e_y \in D_y} E(1(e_y \in \Pi_y(T_{\ell k})))$$

where  $E(\cdot)$  denotes the expectation operator, and  $1(\cdot)$  is the characteristic function taking the value 1 if its argument is true and 0 otherwise.

If  $T_{\ell k}$  satisfies  $x \rightarrow y$  we know that all of the elements of its  $x$ -column must be distinct : otherwise if any two elements were the same, the corresponding  $y$ -column elements would have to be the same and  $T_{\ell k}$  would contain two identical rows which is impossible. On the other hand there may be an arbitrary number of repetitions in the  $y$ -column.

Thus the  $y$ -column of  $T_{\ell k}$  is obtained simply by drawing  $\ell$  elements  $e_y$  from  $D_y$  with repetitions allowed.

We know that

$$e_y \notin \Pi_y(T_{\ell k}) \Leftrightarrow e_y \notin [y\text{-column of } T_{\ell k}]$$

so that the probability of these two events is the same. Hence

$$P[e_y \notin \Pi_y(T_{\ell k})] = \left(1 - \frac{1}{d_y}\right)^\ell$$

which is the probability that  $e_y$  will not be drawn in the  $\ell$  trials, since  $1/d_y$  is the probability of drawing  $e_y$ . But we then have

$$\begin{aligned} E(1(e_y \in \Pi_y(T_{\ell k}))) &= P[e_y \in \Pi_y(T_{\ell k})] \\ &= 1 - P[e_y \notin \Pi_y(T_{\ell k})] = 1 - \left(1 - \frac{1}{d_y}\right)^\ell \end{aligned}$$

Hence

$$\begin{aligned} E_{\ell, k}^y &= \sum_{e_y \in D_y} \left[1 - \left(1 - \frac{1}{d_y}\right)^\ell\right] \\ &= d_y \left[1 - \left(1 - \frac{1}{d_y}\right)^\ell\right] \end{aligned}$$

since  $|D_y| = d_y$ . The approximate formula for  $\ell \ll d_y$  follows from a second order expansion.

3.2. Non-uniform distributions

In many cases of interest uniform distributions over all the tuples are not justified. Take for instance the case of  $T_{\ell k}$  with  $x \rightarrow y$ ,  $x \cup y = t$ ,  $x \cap y = \emptyset$ . We can think of  $x$  as being a key or numbering, while  $y$  can represent a content. In this case a uniform distribution on  $D_y$  is difficult to justify.

Here we shall generalize the results of Section 3.1 to the case where we are given an arbitrary distribution on the elements of  $D_y$  :

$$p(e_y), \quad e_y \in D_y$$

We have an immediate generalisation of COROLLARY 4 ; the proof is very similar.

RESULT 7

$$E_{\ell, k}^y = \sum_{e_y \in D_y} [1 - (1-p(e_y))^{\ell}]$$

The probability distribution of the size of  $\Pi_y(T_{\ell k})$  can also be obtained :

RESULT 8

$$P_{\ell, k}^y(r) = \sum_{\substack{(e^1, \dots, e^r) \\ \in (D_y)^r}} \sum_{\substack{n_i \geq 1 \\ \sum_1^r n_i = \ell}} \frac{\ell!}{n_1! \dots n_r!} \prod_{i=1}^r (p(e^i))^{n_i}$$

where  $(D_y)^r = D_y \times \dots \times D_y$   $r$  times and  $(e^1, \dots, e^r)$  is any vector of  $r$  distinct elements of  $D_y$ . Notice that this reduces to RESULT 3 when  $p(e^i) = 1/d_y$ .

Proof :  $P_{\ell, k}^y(r)$  is the probability that  $\Pi_y(T_{\ell k})$  contains exactly any  $r$  elements of  $D_y$  where  $r \in \ell$ . The probability that it contains  $n_i$  replicates of a given  $e^i \in D_y$ ,  $1 \leq i \leq r$ , is

$$\binom{\ell}{n_1} \left(p(e^1)\right)^{n_1} \binom{\ell-n_1}{n_2} \left(p(e^2)\right)^{n_2} \dots \binom{\ell-n_1-\dots-n_{r-1}}{n_r} \left(p(e^r)\right)^{n_r}$$

where we must have  $n_i \geq 1$ ,  $\sum_1^r n_i = \ell$ . Hence the result.

#### 4. Conclusions

Further results on the size of projections are necessary in the case of more complex systems of functional dependencies.

We think that such results can be obtained. However the price to be paid will reside in some further assumptions concerning the manner in which information is represented in the relations. The recent work of N. SPYRATOS [4] towards the formal representation of data base views provides a promising approach which should be explored.

Another problem which we shall examine in subsequent work is the computation of projections from a dynamic representation of the relation's evolution under the effect of updates.

#### Acknowledgements

The authors thank Ph. RICHARD, M. SPYRATOS, N. SPYRATOS for their comments. The case examined in Section 3.2 was suggested by G. JOMIER.
