Symbolic Computation: Recent Progress and New Frontiers

Paul Zimmermann

INRIA Lorraine/LORIA

SCAN'2002 Conference, Paris, September 23-28, 2002

Abstract

Symbolic computation and computer algebra systems are usually known to be either very slow, or memory expensive. However, some specific symbolic computation problems have received in the last years new algorithmic solutions, which enabled to push further the limits of what is doable within a reasonable amount of time and space. Some noticeable examples are polynomial factorisation, lattice reduction, Gröbner basis computation. We will present a few such algorithms, together with a state-of-the-art of what problems computer algebra systems can (or cannot) solve, and for each problem what the current frontiers are.

Computer Algebra Systems

- **general purpose** (Maple, Mathematica, Macsyma, Reduce, MuPAD, Axiom, Derive):

  proprietary, slow, have known pitfalls

- **special purpose** (GNU MP, Pari, Magma, NTL, Linbox):

  free, fast, fewer bugs?

An Example

Cf. Fabienne Jézéquel talk "*Dynamical control of computations of multiple integrals*" (Tuesday, room Durand):

```
> f := exp(x) * cos(z) + sqrt(y) * sinh(z):
> int(int(int(f, x=2..5), y=1..3), z=2..3);
                        1/2                 1/2
2 exp(5) sin(3) + 3 3    exp(-3) + 3 3    exp(3) - 2 exp(2) sin(3)

                                                    1/2
    - exp(-3) - exp(3) - 2 exp(5) sin(2) - 3 3    exp(2)

        1/2
    - 3 3    exp(-2) + 2 exp(2) sin(2) + exp(2) + exp(-2)
```

```
> evalf(%, 50);
        -163.74566743673553320720440934473233062072278553592

> i := Int(Int(Int(f, x=2..5), y=1..3), z=2..3);
             3    3    5
            /    /    /
           |    |    |                      1/2
           |    |    |   exp(x) cos(z) + y    sinh(z) dx dy dz
           |    |    |
          /    /    /
            2    1    2
> st:=time(): evalf(i), time()-st;
                              -163.7456674, 30.790
```

Pitfalls?

```

```

What size of problem can we solve in one minute?

What size of problem can we solve in one minute?

Computer Characteristics: Pentium II 366Mhz under RedHat 7.2, with gcc 2.95.2, 128MB of main memory, and 256MB of swap.

What kind of problems?

Arithmetics: integer multiplication, gcd, modular exponentiation, floating-point and interval computation.

Number Theory: primality testing, integer factorisation.

Univariate Polynomials: factorisation over $\mathbb{F}_p$ and $\mathbb{Q}$, approximation of complex roots, isolation of real roots.

Linear Algebra: minimal polynomial, determinant, lattice reduction.

Moore's law

The computer power increases by a factor of 2 every 18 months.

CONSEQUENCE: Assume we have a computer whose frequency automatically increases following Moore's law. Then a computation that started at $t = -\infty$ until now can be reproduced in ???

Moore's law

The computer power increases by a factor of 2 every 18 months.

CONSEQUENCE: Assume we have a computer whose frequency automatically increases following Moore's law. Then a computation that started at $t = -\infty$ until now can be reproduced in only 18 months!

Moore's law vs Problem Size

Suppose we can solve in 2002 a problem with 10^{20} bit operations.
How large can we solve in 2010, 2100?

Complexity	2002	2010	2100
n	10^{20}	10^{22}	10^{40}
$n \log n$	10^{18}	10^{20}	10^{38}
n^2	10^{10}	10^{11}	10^{20}
n^3	10^7	10^7	10^{13}
n^6	$2,000$	$4,000$	10^7
$e^{cn^{1/3}\log^{2/3} n}$	159	186	681
2^n	66	72	132
2^{2^n}	6.05	6.17	7.04

Arithmetics: Integer Multiplication

Multiplication of integers has complexity $O(n \log n \log \log n)$ (using FFT). Current multiprecision libraries like GNU MP (GMP) can multiply in one minute (and 87MB) two 21M-digit numbers:

```
ecrouves% ./intmul 21000000
x has 21000007 digits
y has 21000007 digits
x*y took 59040ms
```

Arithmetics: Integer GCD

Integer GCD has asymptotic complexity $O(M(n)\log n)$ where $M(n)$ is the multiplication complexity, *i.e.* $O(n\log^2 n\log\log n)$ using FFT. But the constant is so large that most libraries only implement quadratic algorithms.

Worst case for Euclid's algorithm: $\gcd(F_n, F_{n+1})$. Here with GMP:

```
ecrouves% ./intgcd 717745
Fib[717745] has 150000 digits
gcd(Fib[717745], Fib[717746]) took 12790ms

ecrouves% ./intgcd 1435490
Fib[1435490] has 300000 digits
gcd(Fib[1435490], Fib[1435491]) took 56410ms
```

Magma implements a subquadratic algorithm (but gains only a factor of 2):

```
> n := 2870981;
> x := Fibonacci(n);
> Ceiling(Log(x)/Log(10));
600000
> y := Fibonacci(n+1);
> time z := Gcd(x,y);
Time: 56.540
```

Arithmetics: Modular Exponentiation

Basic routine for RSA: compute $x^y \bmod m$ where both x, y and m have n digits. Theoretical asymptotic complexity is $O(nM(n))$, *i.e.* $\approx n^2 \log n$.

```
ecrouves% ./powm 4300
x has 4305 digits
y has 4306 digits
m has 4306 digits
x^y mod m took 58660ms
```

Arithmetics: Floating-Point Computations

Computation of $\exp(\pi)$ with the MPFR library [complexity $O(M(n)\log^2 n)$]:

```
[zimmerma@ecrouves scan]$ ./exp_pi 200000 > /tmp/exp_pi
mpfr_const_pi took 83770ms
mpfr_exp took 60500ms
mpfr_out_str took 4930ms

% cat /tmp/exp_pi
digits=200000 prec=664386
2.31406926327792690057290863679485473802661062426002119934450464
...
9930270981154056341199492439774176843224931910297732e1
```

Arithmetics: Interval Computations

```
> f := exp(x) * cos(z) + sqrt(y) * sinh(z):
> i:=int(int(int(f, x=2..5), y=1..3), z=2..3):
> codegen[optimize]([res=i]);
                                    1/2
t1 = exp(5), t2 = sin(3), t5 = 3    , t6 = exp(-3), t9 = exp(3),

    t12 = exp(2), t15 = sin(2), t20 = exp(-2), res = 2 t1 t2

     + 3 t5 t6 + 3 t5 t9 - 2 t12 t2 - t6 - t9 - 2 t1 t15 - 3 t5 t12

     - 3 t5 t20 + 2 t12 t15 + t12 + t20
```

With MPFI 1.0 (cf. talk of Nathalie Revol), modified to include the sin function:

```
[zimmerma@ecrouves scan]$ time ./ex_mpfi 33000
Using 109627 bits
res=[-1.637456674...8300366317e2,
     -1.637456674...8300366316e2]
58.690u 0.050s 0:58.92 99.6%    0+0k 0+0io 69pf+0w
```

Number Theory

New: PRIME is in P (Agrawal, Kayal, Saxena, Aug. 2002), but complexity is $O(\log^{12} n)$ (proven) or $O(\log^{6} n)$ (under conjecture)...

ECPP is believed to be $O(\log^{4} n)$. With Morain's ECPP-V6.4.5a:

```
ecrouves% time xrunecpp -f p290 -C p290.cert
Working on 14151327644144748695245001444219656906399186804347542080247 34\

This number is prime
```

Checking the certificate

```
ecrouves% time xcheckcertif -f p290.cert
  0:     43 y       0.60s
...
 57:     -1 y       0.00s

% Total time is       7.72 s
```

```
ecrouves% ./xcheckcertif -f /tmp/cert -v # 572 digits
% Each line has the following shape:
%
% i: D y/n time
% where i is the rank of the certificate,
% D the discriminant
% y if the certificate is correct and n otherwise,
% time is the time needed
  0:    872 y       3.59s
  1:    643 y       3.40s
  2:   1659 y       3.18s
...
 75:     -1 y       0.00s

% Total time is      58.73 s
```

Integer Factorisation

Factor is $O(\exp^{c(\log n)^{1/3}(\log\log n)^{2/3}})$ (Number Field Sieve, Pollard 1988) where the best known $c = \frac{(92+26\sqrt{13})^{1/3}}{3} \approx 1.902$:

```
[zimmerma@ecrouves scan]$ gp

Polynomials: Finding Roots over $\mathbb{F}_p$

Over $\mathbb{F}_p$, the basic operation is $x^p \bmod f$. Von zur Gathen challenge: sparse polynomials $x^n + x + 1$ modulo $p_n = \text{nextprime}(\lfloor \pi 2^n \rfloor)$. With NTL, which implements a $O(n^{1/2} M^2(n))$ algorithm:

```
[zimmerma@ecrouves scan]$ ./findroots 300
[4434586521034737845503930339118996822376578506 6\
    5241640907230010850844609928650296821187046 1
3075860350627550374658971321116944087349369445 46\

3051095390533404789591056039199762033666123832 68\
    0831719240533010715122292526387954862254865] 61.2
```

Magma faster for sparse poly.: 34s for $n = 300$, 59s for $n = 450$.

Shoup: dense polynomials $F_n = \sum a_i x^{n-i}$ modulo
$p_n = \text{nextprime}(\lfloor \pi 2^{n-2} \rfloor)$ (JSC 1995), where $a_0 = 1, a_{i+1} = a_i^2 + 1$:

```
[zimmerma@ecrouves scan]$ ./findroots2 298
[21657151942655967049428580353256300555690137481\
   7989675777685135830817626526417236494974 20] 62.02
```

Factoring over small fields

Factoring F_n mod 3 where F_n is Shoup's polynomial, with Magma [$O(nM(n))$]:

```
> time Shoup_mod3(4000);
[ 1, 3, 30, 201, 611, 645, 1083, 1426 ]
Time: 58.920
```

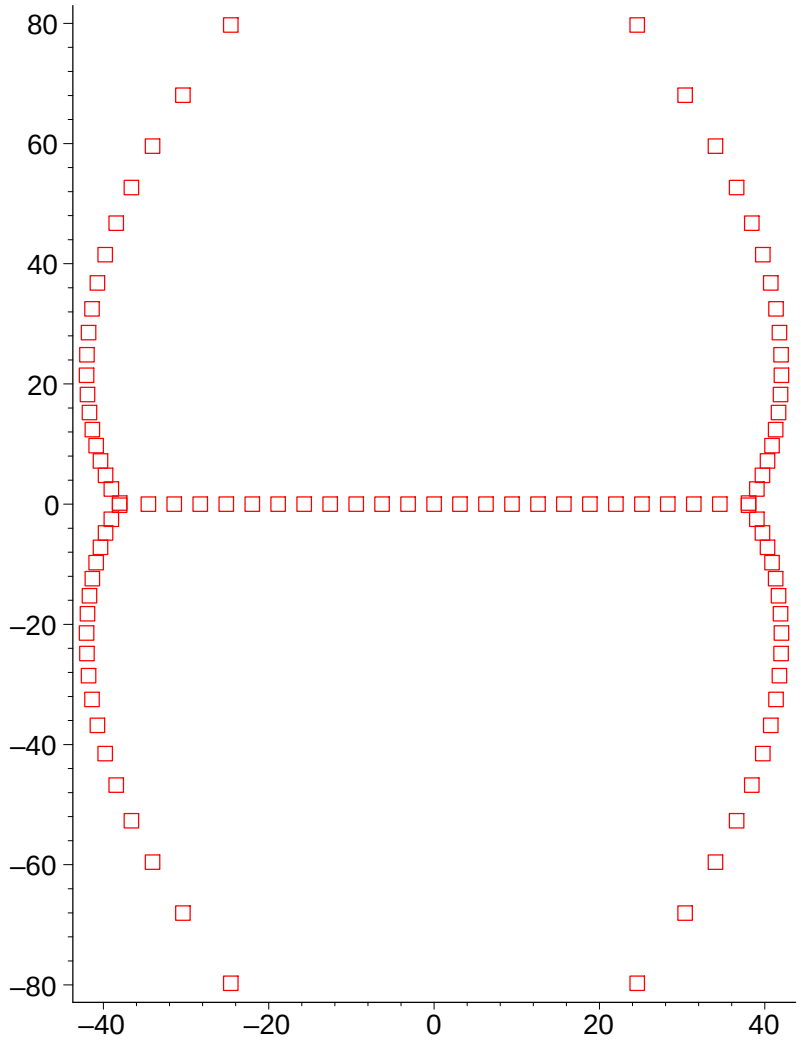
(NTL is much slower: 60s for $n = 1200$, and Pari/GP lies between: 17s for $n = 1200$.)

Factoring over $GF(2)$

Squaring a polynomial takes linear time! Factoring $x^n + x + 1$ takes $\mathcal{O}(n^2)$. With Magma (NTL needs 400s):

```
> time VZG_mod2(21000);
[ 5, 22, 28, 31, 72, 156, 1510, 1855, 6898, 10423 ]
Time: 60.110
```

Complex Roots



Let S_n be the truncated Taylor expansion of order n of $\sin x$ at $x = 0$.

Approximating all complex roots of S_n with MPSolve (Bini, Fiorentino):

```
[zimmerma@ecrouves MPSolve2.0]$ time ./unisolve < sin317
(0, 0)
(-0.13000717252003227 92e3, -0.667510698581253538 5e2)
...
(0.13000717252003227 92e3, -0.667510698581253538 5e2)
60.110u 0.040s 1:00.80 98.9%    0+0k 0+0io 188pf+0w
```

Isolating Real Roots

Uspensky's algorithm based on Descartes' rule (Rouillier, Z., 2002, $O(n^3)$ conjectured):

```
[zimmerma@ecrouves scan]$ time ./usp < sin449
initial interval is -0.1024e4..0.1024e4
1: 0..0
2: -168..-167
...
109: 167..168
109 real root(s)
58.240u 0.010s 0:58.81 99.0%    0+0k 0+0io 47pf+0w
```

Polynomial Factoring

First polynomial algorithm: Lenstra, Lenstra, Lovácz (1982), but impractical [$\mathcal{O}(n^{10})$], even of worst cases for Zassenhaus' exponential algorithm!

van Hoeij (2000): new polynomial algorithm based on LLL, very practical, implemented in NTL.

Factoring $L_n L_{n+1}$ with NTL

$$L_0 = 1, \quad L_1 = 1 - x, \quad nL_n = (2n - 1 - x)L_{n-1} - (n-1)L_{n-2}$$

```
[zimmerma@ecrouves src]$ ./ZZXFacTest < L205_L206
...
*** end SFFactor.  degree sequence:
206 205
total time: 59.38
```

Linear Algebra

Arne Storjohann (ISSAC'02) proved that $A^{-1}b$ and $\det(A)$ over $K[x]^{n\times n}$ have arithmetic complexity $O(n^{\theta}\deg A)$ (Las Vegas model), using "High-Order Lifting".

Seems to extend well to the integer case: $O(n^{\theta})$ bit complexity?

Trefethen's Challenge

Let A be a $n \times n$ sparse matrix with $A_{i,i}$ the ith prime, and $A_{i,j} = 1$ for $|i - j| = 2^k$.

$$
\begin{bmatrix}
2 & 1 & 1 & & 1 & & & & 1 & & & & & & \\
1 & 3 & 1 & 1 & & 1 & & & & 1 & & & & & \\
1 & 1 & 5 & 1 & 1 & & 1 & & & & & 1 & & & \\
 & 1 & 1 & 7 & 1 & 1 & & 1 & & & & & 1 & & \\
1 & & 1 & 1 & 11 & 1 & 1 & & 1 & & & & & 1 & \\
 & 1 & & 1 & 1 & 13 & 1 & 1 & & 1 & & & & & 1 \\
 & & 1 & & 1 & 1 & 17 & 1 & 1 & & 1 & & & & \\
 & & & 1 & & 1 & 1 & 19 & 1 & 1 & & 1 & & & \\
1 & & & & 1 & & 1 & 1 & 23 & 1 & 1 & & 1 & & \\
 & 1 & & & & 1 & & 1 & 1 & 29 & 1 & 1 & & 1 & \\
 & & 1 & & & & 1 & & 1 & 1 & 31 & 1 & 1 & & 1 \\
 & & & 1 & & & & 1 & & 1 & 1 & 37 & 1 & 1 & \\
 & & & & 1 & & & & 1 & & 1 & 1 & 41 & 1 & 1 \\
 & & & & & 1 & & & & 1 & & 1 & 1 & 43 & 1 \\
 & & & & & & 1 & & & & 1 & & 1 & 1 & 47
\end{bmatrix}
$$

The Challenge: for $n = 20000$, compute $B = A^{-1}$, then $B_{1,1}$ (rational with numerator/denominator of $100,000$ digits each). Solved by LinBox in about 2 years of CPU time.

```
[zimmerma@ecrouves blackbox]$ time ./load-det 2500 test.matrix
Massey...Done
Determinant is 665 (mod 65521)

```

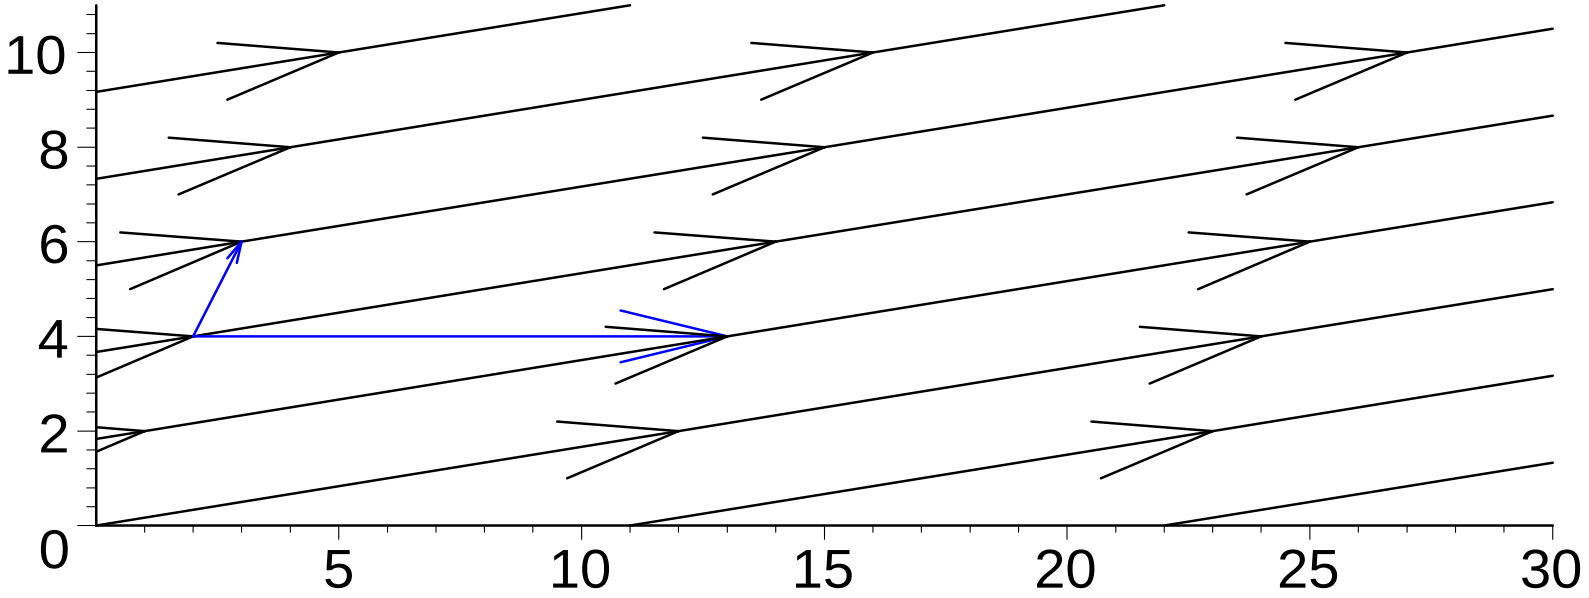
Minimal Polynomial

Compute the minimal polynomial of A mod 65521 (Linbox using black box algorithms):

```
$ time linbox-0.1.2/examples/blackbox/example 3300
Minimal polynomial...done
58.730u 0.030s 0:58.79 99.9%    0+0k 0+0io 194pf+0w
```

Lattice reduction

Problem: given a set of n vectors in $\mathbb{Z}^n$, find a basis of short vectors spanning the same space



Complexity: $\mathcal{O}(n^5 \log^2 A)$ (theoretical) $\mathcal{O}(n^4 \log^2 A)$ (experimental)

New developments: Koy and Schnorr (2002): saves a factor n.

Applications

Knapsack problem: find $\sum_{i=1}^{n} \epsilon_i b_i = S \bmod M$.

```
