**ABSTRACT.** The way the graph structure of the constraints influences the complexity of constraint satisfaction problems (CSP) is well understood for bounded-arity constraints. The situation is less clear if there is no bound on the arities. In this case the answer depends also on how the constraints are represented in the input. We study this question for the truth table representation of constraints. We introduce a new hypergraph measure *adaptive width* and show that CSP with truth tables is polynomial-time solvable if restricted to a class of hypergraphs with bounded adaptive width. Conversely, assuming a conjecture on the complexity of binary CSP, there is no other polynomial-time solvable case.

### 1. Introduction

Constraint satisfaction is a general framework that includes many standard algorithmic problems such as satisfiability, graph coloring, database queries, etc. A constraint satisfaction problem (CSP) consists of a set  $V$  of variables, a domain  $D$ , and a set  $C$  of constraints, where each constraint is a relation on a subset of the variables. The task is to assign a value from  $D$  to each variable such that every constraint is satisfied (see Definition 1.4 for the formal definition). For example, 3SAT can be interpreted as a CSP problem where the domain is  $D = \{0, 1\}$  and the constraints in  $C$  correspond to the clauses.

In general, solving constraint satisfaction problems is NP-hard if there are no additional restrictions on the instances. The main goal of the research on CSP is to identify tractable special cases of the general problem. The theoretical literature on the CSP investigates two main types of restrictions. The first type is to restrict the *constraint language*, that is, the type of constraints that are allowed. The second type is to restrict the *structure* induced by the constraints on the variables. The *hypergraph* of a CSP instance is defined to be a hypergraph on the variables of the instance such that for each constraint  $c \in C$  there is a hyperedge  $E_c$  that contains all the variables that appear in  $c$ . If the hypergraph of the CSP instance has very simple structure, then the instance is easy to solve. For example, it is

well-known that a CSP instance  $I$  with hypergraph  $H$  can be solved in time  $\|I\|^{O(\text{tw}(H))}$  [5], where  $\text{tw}(H)$  denotes the treewidth of  $H$  and  $\|I\|$  is the size of the representation of  $I$  in the input. Thus if we restrict the problem to instances where the treewidth of the hypergraph is bounded by some constant  $w$ , then the problem is polynomial-time solvable. The aim of this paper is to investigate whether there exists some other structural property of the hypergraph besides bounded treewidth that makes the problem tractable. Formally, for a class  $\mathcal{H}$  of hypergraphs, let  $\text{CSP}(\mathcal{H})$  be the restriction of CSP where the hypergraph of the instance is assumed to be in  $\mathcal{H}$ . Our goal is to characterize the complexity of  $\text{CSP}(\mathcal{H})$  for every class  $\mathcal{H}$ .

We investigate two notions of tractability.  $\text{CSP}(\mathcal{H})$  is *polynomial-time solvable* if every instance of  $\text{CSP}(\mathcal{H})$  can be solved in time  $(\|I\|)^{O(1)}$ , where  $\|I\|$  is the length of the representation of  $I$  in the input. The following notion interprets tractability in a less restrictive way:  $\text{CSP}(\mathcal{H})$  is *fixed-parameter tractable (FPT)* if there is a function  $f$  such that every instance  $I$  of  $\text{CSP}(\mathcal{H})$  can be solved in time  $f(H)(\|I\|)^{O(1)}$ , where  $H$  is the hypergraph of the instance. Equivalently, the factor  $f(H)$  in the definition can be replaced with a factor  $f(k)$  depending only on the number  $k$  of vertices of  $H$ : as the number of hypergraphs on  $k$  vertices is bounded by a function of  $k$ , the two definitions result in the same notion. The motivation behind the definition of fixed-parameter tractability is that in certain applications we expect the domain size to be much larger than the number of variables, hence a constant factor in the running time depending only on the number of variables (or on the hypergraph) is acceptable. For more background on fixed-parameter tractability, see [3, 4].

**Bounded arities.** If the constraints have bounded arity (i.e., edge size in  $\mathcal{H}$  is bounded by a constant), then the complexity of  $\text{CSP}(\mathcal{H})$  is well understood:

**Theorem 1.1** ([7]). *If  $\mathcal{H}$  is a recursively enumerable class of hypergraphs with bounded edge size, then (assuming  $\text{FPT} \neq \text{W}[1]$ ) the following are equivalent:*

- (1)  $\text{CSP}(\mathcal{H})$  is polynomial-time solvable.
- (2)  $\text{CSP}(\mathcal{H})$  is fixed-parameter tractable.
- (3)  $\mathcal{H}$  has bounded treewidth.

The assumption  $\text{FPT} \neq \text{W}[1]$  is a standard hypothesis of parameterized complexity. Thus in the bounded arity case bounded treewidth is the only property of the hypergraph that can make the problem polynomial-time solvable. Furthermore, the following sharpening of Theorem 1.1 shows that there is no algorithm whose running time is significantly better than the  $\|I\|^{O(\text{tw}(H))}$  bound of the treewidth based algorithm. The result is proved under the Exponential Time Hypothesis (ETH) [9]: it is assumed that there is no  $2^{o(n)}$  time algorithm for  $n$ -variable 3SAT.

**Theorem 1.2** ([11]). *If there is a computable function  $f$  and a recursively enumerable class  $\mathcal{H}$  of hypergraphs with bounded edge size and unbounded treewidth such that the problem  $\text{CSP}(\mathcal{H})$  can be solved in time  $f(H)\|I\|^{o(\text{tw}(H)/\log \text{tw}(H))}$  for instances  $I$  with hypergraph  $H \in \mathcal{H}$ , then ETH fails.*

This means that the treewidth-based algorithm is almost optimal: in the exponent only an  $O(\log \text{tw}(H))$  factor improvement is possible. It is conjectured in [11] that Theorem 1.2 can be made tight:

**Conjecture 1.3** ([11]). *If  $\mathcal{H}$  is a class of hypergraphs with bounded edge size, then there is no algorithm that solves  $\text{CSP}(\mathcal{H})$  in time  $f(H)\|I\|^{o(\text{tw}(H))}$  for instances  $I$  with hypergraph  $H \in \mathcal{H}$ , where  $f$  is an arbitrary computable function.*

**Unbounded arities.** The situation is less understood in the unbounded arity case, i.e., when there is no bound on the maximum edge size in  $\mathcal{H}$ . First, the complexity in the unbounded-arity case depends on how the constraints are represented. In the bounded-arity case, if each constraint contains at most  $r$  variables ( $r$  being a fixed constant), then every reasonable representation of a constraint has size  $|D|^{O(r)}$ . Therefore, the size of the different representations can differ only by a polynomial factor. On the other hand, if there is no bound on the arity, then there can be exponential difference between the size of succinct representations (e.g., formulas) and verbose representations (e.g., truth tables). The running time is expressed as a function of the input size, hence the complexity of the problem can depend on how the input is represented: longer representation means that it can be easier to obtain a polynomial-time algorithm.

The most well-studied representation of constraints is listing all the tuples that satisfy the constraint. For this representation, there are classes  $\mathcal{H}$  with unbounded treewidth such that CSP restricted to this class is polynomial-time solvable. For example, classes with bounded (*generalized*) *hypertree width* [6], bounded *fractional edge cover number* [8], and bounded *fractional hypertree width* [8, 10] are such classes. However, no classification theorem similar to Theorem 1.1 is known for this version. More succinct representations were studied by Chen and Grohe [2]: constraints are represented by generalized DNF formulas and ordered binary decision diagrams (OBDD). The complexity of the problem with this representation was fully characterized: the complexity depends not on the treewidth of the hypergraph, but on the treewidth of the incidence structure.

**Truth table representation.** In this paper we study another natural representation: truth tables. A constraint of arity  $r$  is represented by having one bit for each possible  $r$ -tuple that can appear on the  $r$  variables of the constraint, and this bit determines whether this particular  $r$ -tuple satisfies the constraint or not. To increase the flexibility of the representation and make it more natural, we allow that the variables have different domains, i.e., each variable  $v$  has to be assigned a value from its domain  $\text{Dom}(v)$ . Thus the size of the truth table of an  $r$ -ary constraint is proportional to the size of the direct product of the domains of the  $r$  variables. This representation is more verbose than listing satisfying tuples: the size of the representation is proportional to the number of possible tuples even if only few tuples satisfy the constraint. We define CSP as follows:

**Definition 1.4.** A CSP instance is a quadruple  $(V, D, \text{Dom}, C)$ , where:

- $V$  is a set of variables,
- $D$  is a domain of values,
- $\text{Dom} : V \rightarrow 2^D$  assigns a domain  $\text{Dom}(v) \subseteq D$  to each variable  $v \in V$ ,
- $C$  is a set of constraints. Each  $c_i \in C$  is a pair  $\langle s_i, R_i \rangle$ , where:
  - $s_i = (u_{i,1}, \dots, u_{i,m_i})$  is a tuple of variables (the *constraint scope*), and
  - $R_i$  is a subset of  $\prod_{j=1}^{m_i} \text{Dom}(u_{i,j})$  (the *constraint relation*).

For each constraint  $\langle s_i, R_i \rangle$  the tuples of  $R_i$  indicate the allowed combinations of values for the variables in  $s_i$ . The length  $m_i$  of the tuple  $s_i$  is called the *arity* of the constraint. A *solution* to a CSP instance is a function  $f : V \rightarrow D$  such that  $f(v) \in \text{Dom}(v)$  for every  $v \in V$  and for each constraint  $\langle s_i, R_i \rangle$  with  $s_i = \langle u_{i,1}, u_{i,2}, \dots, u_{i,m_i} \rangle$ , the tuple  $\langle f(u_{i,1}), f(u_{i,2}), \dots, f(u_{i,m_i}) \rangle$  is in  $R_i$ .

We denote by  $\text{CSP}_{\text{tt}}$  the problem where each constraint  $\langle s_i, R_i \rangle$  of arity  $m_i$  is represented by the truth table of the constraint relation  $R_i$ , that is, by a sequence of  $\prod_{j=1}^{m_i} |\text{Dom}(u_{i,j})|$

bits that describe that subset  $R_i$  of  $\prod_{j=1}^{m_i} \text{Dom}(u_{i,j})$ . For a class  $\mathcal{H}$ ,  $\text{CSP}_{\text{tt}}(\mathcal{H})$  is the restriction to instances with hypergraph in  $\mathcal{H}$ .

**Results.** The main result of the paper is a complete characterization of the complexity of  $\text{CSP}_{\text{tt}}(\mathcal{H})$  (assuming Conjecture 1.3). The complexity of the problem depends on a new hypergraph measure *adaptive width*:

**Theorem 1.5 (Main).** *Assuming Conjecture 1.3, the following are equivalent:*

- (1)  $\text{CSP}_{\text{tt}}(\mathcal{H})$  is polynomial-time solvable.
- (2)  $\text{CSP}_{\text{tt}}(\mathcal{H})$  is fixed-parameter tractable.
- (3)  $\mathcal{H}$  has bounded adaptive width.

The assumption in Theorem 1.5 is nonstandard, so it is up to the reader to decide how strong this evidence is. However, the message of Theorem 1.5 is the following: a new tractable class for  $\text{CSP}_{\text{tt}}(\mathcal{H})$  would imply surprising new results for *binary* CSP. Thus it is not worth putting too much effort in further studying  $\text{CSP}_{\text{tt}}(\mathcal{H})$  with the hope of finding new tractable classes: as this would disprove Conjecture 1.3, such an effort would be better spent trying to disprove Conjecture 1.3 directly, by beating the  $\|I\|^{O(\text{tw}(H))}$  algorithm for binary CSP.

Listing the satisfying tuples is a more succinct representation of a constraint than a truth table. Thus if CSP is polynomial-time solvable or fixed-parameter tractable for some class  $\mathcal{H}$  with the former representation, then this also holds for the latter representation as well. In particular, this means that by the results of [8, 10],  $\text{CSP}_{\text{tt}}(\mathcal{H})$  is polynomial-time solvable if  $\mathcal{H}$  has bounded fractional hypertree width. This raises the question whether Theorem 1.5 gives any new tractable class  $\mathcal{H}$ . In other words, is there a class  $\mathcal{H}$  having bounded adaptive width but unbounded fractional hypertree width? In Section 5, we answer this question by constructing such a class  $\mathcal{H}$ . This means that  $\text{CSP}_{\text{tt}}(\mathcal{H})$  is polynomial-time solvable, but if the constraints are represented by listing the satisfying tuples, then it is not even known whether the problem is FPT.

## 2. Width parameters

Treewidth and various variants are defined in this section. We follow the framework of width functions introduced by Adler [1]. A *tree decomposition* of a hypergraph  $H$  is a tuple  $(T, (B_t)_{t \in V(T)})$ , where  $T$  is a tree and  $(B_t)_{t \in V(T)}$  is a family of subsets of  $V(H)$  such that for each  $E \in E(H)$  there is a node  $t \in V(T)$  such that  $E \subseteq B_t$ , and for each  $v \in V(H)$  the set  $\{t \in V(T) \mid v \in B_t\}$  is connected in  $T$ . The sets  $B_t$  are called the *bags* of the decomposition. Let  $f : 2^{V(H)} \rightarrow \mathbb{R}^+$  be a function that assigns a real number to each subset of vertices. The *f-width* of a tree-decomposition  $(T, (B_t)_{t \in V(T)})$  is  $\max \{f(B_t) \mid t \in V(T)\}$ . The *f-width* of a hypergraph  $H$  is the minimum of the *f-widths* of all its tree decompositions.

**Definition 2.1.** Let  $s(B) = |B| - 1$ . The *treewidth* of  $H$  is  $\text{tw}(H) := s\text{-width}(H)$ .

A subset  $E' \subseteq E(H)$  is an *edge cover* if  $\bigcup E' = V(H)$ . The *edge cover number*  $\rho(H)$  is the size of the smallest edge cover (assuming  $H$  has no isolated vertices). For  $X \subseteq V(H)$ , let  $\rho_H(X)$  be the size of the smallest set of edges covering  $X$ .

**Definition 2.2.** The (*generalized*) *hypertree width* of  $H$  is  $\text{hw}(H) := \rho_H\text{-width}(H)$ .

We also consider the linear relaxations of edge covers: a function  $\gamma : E(H) \rightarrow [0, 1]$  is a *fractional edge cover* of  $H$  if  $\sum_{E:v \in E} \gamma(E) \geq 1$  for every  $v \in V(H)$ . The *fractional*

cover number  $\rho^*(H)$  of  $H$  is the minimum of  $\sum_{E \in E(H)} \gamma(E)$  taken over all fractional edge covers of  $H$ . We define  $\rho_H^*(X)$  analogously to  $\rho_H(X)$ : the requirement  $\sum_{E: v \in E} \gamma(E) \geq 1$  is restricted to vertices of  $X$ .

**Definition 2.3.** The *fractional hypertree width* of  $H$  is  $\text{fhw}(H) := \rho_H^*$ -width( $H$ ).

The dual of covering is independence. A subset  $X \subseteq V(H)$  is an *independent set* if  $|X \cap E| \leq 1$  for every  $E \in E(H)$ . The *independence number*  $\alpha(H)$  is the size of the largest independent set and  $\alpha_H(X)$  is the size of the largest independent set that is a subset of  $X$ . A function  $\phi : V(H) \rightarrow [0, 1]$  is a *fractional independent set* of the hypergraph  $H$  if  $\sum_{v \in E} \phi(v) \leq 1$  for every  $E \in E(H)$ . The *fractional independence number*  $\alpha^*(H)$  of  $H$  is the maximum of  $\sum_{v \in V(H)} \phi(v)$  taken over all fractional independent sets  $\phi$  of  $H$ . It is well-known that  $\alpha(H) \leq \alpha^*(H) = \rho^*(H) \leq \rho(H)$  for every hypergraph  $H$ . Thus  $\alpha^*$ -width gives us the same notion as fractional hypertree width. The main new definition of the paper uses fractional independent sets, but in a different way. For a function  $f : V(H) \rightarrow \mathbb{R}^+$ , we define  $f(X) = \sum_{v \in X} f(v)$  for  $X \subseteq V(H)$  and define  $f$ -width accordingly.

**Definition 2.4.** The *adaptive width*  $\text{adw}(H)$  of a hypergraph  $H$  is the maximum of  $\phi$ -width( $H$ ) taken over all fractional independent sets  $\phi$  of  $H$ .

Currently, we do not have an efficient algorithm for computing adaptive width. Fortunately, the polynomial-time algorithm in Section 3 for instances with bounded adaptive width does not need to determine the adaptive width of the input, it is sufficient that the adaptive width is promised to be bounded. However, the hardness proof of Section 4 requires that the question  $\text{adw}(H) \geq w$  is decidable (proof is omitted).

**Lemma 2.5.** *There is an algorithm that, given hypergraph  $H$  and rational number  $w$ , decides if  $\text{adw}(H) \geq w$ . If the answer is yes, then the algorithm returns a rational fractional independent set  $\alpha$  such that the  $\alpha$ -width of  $H$  is at least  $w$ .*

We finish the section with a combinatorial observation (the closed neighborhood of a vertex  $v$  is the union of all the edges containing  $v$ ):

**Lemma 2.6.** *Given a tree decomposition of hypergraph  $H$ , it can be transformed in polynomial time (by removing vertices from some bags) into a tree decomposition of  $H$  satisfying the following property: if two adjacent vertices  $u$  and  $v$  have the same closed neighborhood, then  $u$  and  $v$  appear in exactly the same bags.*

*Proof.* Consider a tree decomposition of  $H$ . If  $u$  and  $v$  are two vertices that do not satisfy the requirements, then remove these vertices from those bags where only one of them appears (since  $u$  and  $v$  are neighbors, they appear together in some bag  $B_t$ , hence both vertices appear in at least one bag after the removals). The intersection of two subtrees is also a subtree, thus it remains true that  $u$  and  $v$  appear in a connected subset of the bags. We have to show that for every edge  $E \in E(H)$ , there is a bag  $B_t$  that fully contains  $E$  even after the removals. If  $\{u, v\} \subseteq E$  or  $E \cap \{u, v\} = \emptyset$ , then this clearly follows from that fact that some bag fully contains  $E$  before the removals. Assume without loss of generality that  $u \in E$  and  $v \notin E$ . We show that  $E \cup \{v\}$  is fully contained in some bag  $B_t$  before the removals, hence (as  $\{u, v\} \subseteq E \cup \{v\}$ )  $B_t$  fully contains  $E \cup \{v\}$  even after the removals. Since  $u \in E$ , edge  $E$  is in the closed neighborhood of  $v$ . Thus by assumption,  $E$  is also in the closed neighborhood of  $v$ , which means that  $E \cup \{v\}$  is a clique in  $H$ . It is well known that every clique is fully contained in some bag of the tree decomposition (this follows from

the fact that subtrees of a tree satisfy the Helly property), thus it follows that  $E \cup \{v\} \subseteq B_t$  for some bag  $B_t$ .

Let us repeat these removals until there are no pairs  $u, v$  that violate the requirements; eventually we get a tree decomposition as required. Observe that the procedure terminates after a polynomial number of steps: vertices are only removed from the bags. ■

### 3. Algorithm for bounded adaptive width

We prove that  $\text{CSP}_{\text{tt}}(\mathcal{H})$  is polynomial-time solvable if  $\mathcal{H}$  has bounded adaptive width. Bounded adaptive width ensures that no matter what the distribution of the domain sizes in the input instance is, there is a decomposition where the variables in each bag have only a polynomial number of possible assignments. For such a decomposition, the instance can be solved by standard techniques.

**Lemma 3.1.** *There is an algorithm that, given an instance  $I$  of  $\text{CSP}_{\text{tt}}$ , an integer  $C$ , and a tree decomposition  $(T, (B_t)_{t \in V(T)})$  of the hypergraph  $H$  of the instance such that  $\prod_{v \in B_t} |\text{Dom}(v)| \leq C$  for every bag  $B_t$ , solves the instance  $I$  in time polynomial in  $\|I\| \cdot C$ .*

*Proof.* If  $\prod_{v \in B_t} |\text{Dom}(v)| \leq C$ , then there are at most  $C$  possible assignments on the variables in  $B_t$ . Using standard dynamic programming techniques, it is easy to check whether it is possible to select one assignment  $f_t$  for each bag  $B_t$  such that  $f_t$  satisfies the instance induced by the bag  $B_t$  and these assignments are compatible. For completeness, we briefly describe how this can be done by a reduction to binary CSP.

Let us construct a binary CSP instance  $I'$  as follows. The set of variables of  $I'$  is  $V(T)$ , i.e., the bags of the tree decomposition. For  $t \in V(T)$ , let  $b_t \leq C$  be the number of assignments  $f$  to the variables in  $B_t$  such that  $f(v) \in \text{Dom}(v)$  for every  $v \in B_t$ ; denote by  $f_{t,i}$  the  $i$ -th such assignment on  $B_t$  ( $1 \leq i \leq b_t$ ). The domain of  $I'$  is  $D' = \{1, \dots, C\}$ . For each edge  $t't'' \in E(T)$ , we introduce a constraint  $c_{t',t''} = \langle (t', t''), R_{t',t''} \rangle$ , where  $(i, j) \in R_{t',t''}$  if and only if

- $f_{t',i}$  and  $f_{t'',j}$  are compatible, i.e.,  $f_{t',i}(v) = f_{t'',j}(v)$  for every  $v \in B_{t'} \cap B_{t''}$ .
- $f_{t',i}$  satisfies every constraints of  $I$  whose scope is contained in  $B_{t'}$ .
- $f_{t'',j}$  satisfies every constraints of  $I$  whose scope is contained in  $B_{t''}$ .

It is easy to see that a solution of  $I'$  determines a solution of  $I$ . The size of  $I'$  is polynomial in  $C$  and  $\|I\|$ . Since the graph of  $I'$  is a tree, it can be solved in time  $\|I'\|^{O(1)} = (\|I\|C)^{O(1)}$ . ■

**Theorem 3.2.** *If  $\mathcal{H}$  has bounded adaptive width, then  $\text{CSP}_{\text{tt}}(\mathcal{H}) \in \text{PTIME}$ .*

*Proof.* Let  $I$  be an instance of  $\text{CSP}_{\text{tt}}(\mathcal{H})$  with hypergraph  $H$  such that  $\text{adw}(H) \leq c$ . Let  $N \leq \|I\|$  be the size of the largest truth table in the input; we assume that  $N > 1$ , since the problem is trivial if  $N = 1$ . We show that it is possible to find in time  $N^{O(c)}$  a tree decomposition  $(T, B_{t \in V(T)})$  of the instance such that  $\prod_{v \in B_t} |\text{Dom}(v)| \leq N^{O(c)}$  holds for every bag  $B_t$ . By Lemma 3.1, this means that the instance can be solved in time polynomial in  $\|I\|$  and  $N^{O(c)}$ , i.e., the running time is  $\|I\|^{O(c)}$ .

Let  $\phi(v) = \log_2 |\text{Dom}(v)| / \log_2 N$ . We claim that  $\phi$  is a fractional independent set of  $H$ . If there is a constraint with  $(v_{i_1}, v_{i_2}, \dots, v_{i_r})$  such that  $\sum_{j=1}^r \phi(v_j) > 1$ , then the size of the truth table describing the constraint is larger than  $N$ :

$$\prod_{j=1}^r |\text{Dom}(i_j)| = \prod_{j=1}^r 2^{\phi(v_{i_j}) \cdot \log_2 N} = 2^{\log_2 N \cdot \sum_{j=1}^r \phi(v_{i_j})} > 2^{\log_2 N} = N.$$

Define  $\phi'(v) = \lceil \phi(v) \log_2 N \rceil$ . Observe that  $\phi(v) \geq 1/\log_2 N$ , hence  $\phi'(v) < 2\phi(v) \log_2 N$  (if  $|\text{Dom}(v)| = 1$ , then the instance can be simplified). Let  $H'$  be the hypergraph that is obtained from  $H$  by replacing each vertex  $v$  with a set  $X_v$  of  $\phi'(v)$  vertices; if an edge  $E$  contains some vertex  $v$  in  $H$ , then  $E$  contains every vertex of  $X_v$  in  $H'$ . We claim that  $H'$  has treewidth less than  $2c \log_2 N$ . Since  $\text{adw}(H) \leq c$ ,  $H$  has a tree decomposition  $(T, B_{t \in V(T)})$  such that  $\sum_{v \in B_t} \phi(v) \leq c$  holds for every bag  $B_t$ . Consider the analogous decomposition  $(T, B'_{t \in V(T)})$  of  $H'$ ; i.e., if a bag  $B_t$  contains a vertex  $v$  of  $H$ , then let bag  $B'_t$  contain every vertex of  $X_v$ . The size of a bag  $B'_t$  is  $\sum_{v \in B_t} |X_v| = \sum_{v \in B_t} \phi'(v) \leq 2 \log_2 N \cdot \sum_{v \in B_t} \phi(v) \leq 2c \log_2 N$ , thus the treewidth of  $H'$  is indeed less than  $2c \log_2 N$ . Given a graph  $G$  with  $n$  vertices, it is possible to find a tree decomposition of width at most  $4 \text{tw}(G) + 1$  in time  $2^{O(\text{tw}(G))} n^{O(1)}$  (see e.g., [4, Prop. 11.14]). Thus we can find a tree decomposition  $(T, B''_{t \in V(T)})$  of width at most  $8c \log_2 N$  for  $H'$  in time  $2^{O(2c \log_2 N)} \|H'\|^{O(1)} = N^{O(c)} \|H'\|^{O(1)}$ .

In  $H'$ , every vertex of  $X_v$  is contained in the same set of edges. By Lemma 2.6, it can be assumed that each bag of  $(T, B''_{t \in V(T)})$  contains either all or none of  $X_v$ . Define the tree decomposition  $(T, B^*_{t \in V(T)})$  of  $H$  where bag  $B^*_t$  contains  $v$  if and only if  $X_v$  is contained in  $B''_t$ . The  $\phi$ -weight of a bag  $B^*_t$  can be bounded as

$$\sum_{v \in B^*_t} \phi(v) \leq \frac{1}{\log_2 N} \sum_{v \in B^*_t} \phi'(v) = \frac{1}{\log_2 N} |B''_t| \leq 8c.$$

Thus in the tree decomposition  $(T, B^*_{t \in V(T)})$ , the product of the domain sizes is

$$\prod_{v \in B^*_t} |\text{Dom}(v)| = \prod_{v \in B^*_t} 2^{\phi(v) \cdot \log_2 N} = 2^{\log_2 N \cdot \sum_{v \in B^*_t} \phi(v)} \leq 2^{\log_2 N \cdot 8c} = N^{8c},$$

in each bag  $B^*_t$ , as required. ■

#### 4. Hardness result for unbounded adaptive width

We prove the main complexity result of the paper in this section.

**Theorem 4.1.** *Let  $\mathcal{H}$  be a recursively enumerable class of hypergraphs with unbounded adaptive width. Assuming Conjecture 1.3,  $\text{CSP}_{\text{tt}}(\mathcal{H})$  is not FPT.*

*Proof.* Suppose that  $\text{CSP}_{\text{tt}}(\mathcal{H})$  can be solved in time  $h_1(H) \|I\|^c$  for some constant  $c$  and computable function  $h_1$ . Let us fix an arbitrary computable enumeration of the hypergraphs in  $\mathcal{H}$ . For every  $k \geq 1$ , let  $H_k$  be the first hypergraph in this enumeration with  $\text{adw}(H_k) \geq k$ . For each  $k \geq 1$ , let  $\phi_k$  be the fractional independent set returned by the algorithm of Lemma 2.5 for the question ‘ $\text{adw}(H_k) \geq k$ ?’.

**Constructing the graph class  $\mathcal{G}$ .** For each  $k \geq 1$ , we construct a graph  $G_k$  based on  $H_k$  and  $\phi_k$ . Let  $q_k$  be the least common denominator of the rational values  $\phi_k(v)$  for  $v \in V(H_k)$ . The graph  $G_k$  has a clique  $K_v$  of size  $q_k \cdot \phi(v)$  for each  $v \in V(H_k)$  and if  $u$  and  $v$  are neighbors in  $H_k$ , then every vertex of  $K_u$  is connected to every vertex of  $K_v$ . Let  $\mathcal{G} = \{G_k \mid k \geq 1\}$ .

We claim that  $\text{tw}(G_k) \geq q_k k - 1$ . Suppose for contradiction that  $G_k$  has a tree decomposition  $(T, (B_t)_{t \in V(T)})$  of width less than  $q_k k - 1$ , i.e., the size of every bag is smaller than  $q_k k$ . By Lemma 2.6, it can be assumed that for every  $v \in V(H_k)$  and bag  $B_t$  of

the decomposition, either  $B_t$  fully contains  $K_v$  or disjoint from it. Let us construct a tree decomposition  $(T, (B'_t)_{t \in V(T)})$  of  $H_k$  such that  $B'_t$  contains  $v$  if and only if  $B_t$  fully contains  $K_v$ . It is easy to see that this is a tree decomposition of  $H_k$ : for every  $E \in E(H_k)$ , the set  $\bigcup_{v \in E} K_v$  is a clique in  $G_k$ , hence there is a bag  $B_t$  containing  $\bigcup_{v \in E} K_v$ , i.e.  $B'_t$  contains  $E$ . Furthermore,  $\phi_k(B'_t) < k$  for every bag  $B'_t$ : if  $\phi_k(B'_t) \geq k$ , then  $|\bigcup_{v \in E} K_v| \geq q_k k$ , contradicting the assumption that every bag  $B_t$  has size strictly less than  $q_k k$ . This would contradict the assumption  $\text{adw}(H_k) \geq k$ , thus  $\text{tw}(G_k) \geq q_k k - 1$ .

**Simulating  $G_k$  by  $H_k$ .** We present an algorithm for  $\text{CSP}(\mathcal{G})$  violating Conjecture 1.3. We show how a binary  $\text{CSP}(\mathcal{G})$  instance  $I_1$  with graph  $G_k$  can be reduced to a  $\text{CSP}_{\text{tt}}(\mathcal{H})$  instance  $I_2$  with hypergraph  $H_k \in \mathcal{H}$ . Then  $I_2$  can be solved with the assumed algorithm for  $\text{CSP}_{\text{tt}}(\mathcal{H})$ . Let  $G \in \mathcal{G}$  be the graph of the  $\text{CSP}$  instance  $I_1$ . By enumerating the hypergraphs in  $\mathcal{H}$ , we can find the first value  $k$  such that  $G = G_k$ . We construct a  $\text{CSP}_{\text{tt}}(\mathcal{H})$  instance  $I_2$  with hypergraph  $H_k$  where every variable  $v \in V(H_k)$  simulates the variables in  $K_v$ .

The domain  $\text{Dom}(v)$  of  $v$  is  $D^{|K_v|}$ , i.e.,  $\text{Dom}(v)$  is the set of  $|K_v|$ -tuples of  $D$ . For every  $v \in V(H_k)$ , there is a natural bijection between the elements of  $\text{Dom}(v)$  and the  $|D|^{|K_v|}$  possible assignments  $f : K_v \rightarrow D$ . For each edge  $E = (v_1, \dots, v_r) \in E(H_k)$ , we add a constraint  $c_E = \langle (v_1, \dots, v_r), R_E \rangle$  to  $I_2$  as follows. Let  $(x_1, \dots, x_r) \in \prod_{i=1}^r \text{Dom}(v_i)$ . For  $1 \leq i \leq r$ , let  $g_i$  be the assignment of  $K_{v_i}$  corresponding to  $x_i \in \text{Dom}(v_i)$ . These  $r$  assignments together define an assignment  $g : \bigcup_{i=1}^r K_{v_i} \rightarrow D$  on the union of their domains. We define the relation  $R_E$  such that  $(x_1, \dots, x_r)$  is a member of  $R_E$  if and only if the corresponding assignment  $g$  satisfies every constraint of  $I_1$  whose scope is contained in  $\bigcup_{i=1}^r K_{v_i}$ .

Assume that  $I_1$  has a solution  $f_1 : V(G_k) \rightarrow D$ . For every  $v \in V(H_k)$ , define  $f_2(v)$  to be the member of  $\text{Dom}(v)$  corresponding to the assignment  $f_1$  restricted to  $K_v$ . Now  $f_2$  is a solution of  $I_2$ : for every edge  $E$  of  $H_k$ , assignment  $f_1$  restricted to  $\bigcup_{v \in E} K_v$  clearly satisfies every constraint of  $I_1$  whose scope is in  $\bigcup_{v \in E} K_v$ .

Assume now that  $I_2$  has a solution  $f_2 : V_2 \rightarrow D_2$ . For every  $v \in V(H_k)$ , there is an assignment  $f_v : K_v \rightarrow D$  corresponding to the value  $f_2(v)$ . These assignments together define an assignment  $f_1 : V(G_k) \rightarrow D$ . We claim that  $f_1$  is a solution of  $I_1$ . Let  $c = \langle (u', v'), R \rangle$  be an arbitrary constraint of  $I_1$ . Assume that  $u' \in K_u$  and  $v' \in K_v$  for some  $u, v \in V(H_k)$ . Since  $u'v' \in E(G_k)$ , there is an edge  $E \in E(H_k)$  with  $u, v \in E$ . The definition of  $c_E$  in  $I_2$  ensures that  $f_1$  restricted to  $K_u \cup K_v$  satisfies every constraint of  $I_1$  whose scope is contained in  $K_u \cup K_v$ ; in particular,  $f_1$  satisfies constraint  $c$ .

**Running time.** Assume that an instance  $I_1$  of  $\text{CSP}(\mathcal{G})$  is solved by first reducing it to an instance  $I_2$  as above and then applying the algorithm for  $\text{CSP}_{\text{tt}}(\mathcal{H})$ . Let us determine the running time of this algorithm. The first step of the algorithm is to enumerate the hypergraphs in  $\mathcal{H}$  until the correct value of  $k$  is found. The time required by this step depends only on the graph  $G \in \mathcal{G}$ ; denote it by  $h_2(G)$ . Let us determine the time required to construct instance  $I_2$  and the size of the representation of  $I_2$ . As defined above, for each constraint  $c_E$  in  $I_2$ , we have to enumerate every tuple  $(x_1, \dots, x_r) \in \prod_{i=1}^r \text{Dom}(v)$  and check whether the corresponding assignment  $g$  is a solution of the instance  $I_1[\bigcup_{i=1}^r K_{v_i}]$ . Checking a vector  $(x_1, \dots, x_r)$  can be done in time polynomial in  $\|I_1\|$ . Moreover,

$$\left| \prod_{i=1}^r \text{Dom}(v) \right| = \prod_{i=1}^r |D|^{|K_{v_i}|} = \prod_{i=1}^r |D|^{q_k \cdot \phi_k(v_i)} = |D|^{q_k \sum_{i=1}^r \phi_k(v_i)} \leq |D|^{q_k},$$

since  $\phi_k$  is a fractional independent set and  $\{x_1, \dots, x_r\}$  is an edge of  $H_k$ . Every other step is polynomial in  $\|I_1\|$ , hence the reduction can be done in time  $h_2(G)\|I_1\|^{O(q_k)}$ , which is also a bound on  $\|I_2\|$ . Thus the algorithm for  $\text{CSP}_{\text{tt}}(\mathcal{H})$  requires  $h_1(H_k)(h_2(G)\|I_1\|)^{O(q_k c)}$  time, yielding a total time of  $h_3(G)\|I_1\|^{O(q_k c)}$  for some computable function  $h_3$ .

We show that  $\|I_1\|^{O(q_k c)}$  is  $\|I_1\|^{o(\text{tw}(G_k))}$ , violating Conjecture 1.3. Let  $s(w)$  be the smallest  $k$  such that  $\text{tw}(G_k)$  is greater than  $w$  (as  $\text{tw}(G_k) \geq q_k k - 1$ , this is well defined). Observe that  $s(w)$  is nondecreasing and unbounded. We have

$$\|I_1\|^{O(q_k c)} \leq \|I_1\|^{O(c(\text{tw}(G_k)+1)/k)} \leq \|I_1\|^{O(c(\text{tw}(G)+1)/s(\text{tw}(G)))} = \|I_1\|^{o(\text{tw}(G))}.$$

Thus the total running time is  $h_3(G)\|I_1\|^{o(\text{tw}(G))}$ , violating Conjecture 1.3. ■

### 5. Relation of bounded fractional hypertree width and bounded adaptive width

We show that the class of sets of hypergraphs with bounded adaptive width strictly includes the class of sets with bounded fractional hypertree width. First, fractional hypertree width is an upper bound for adaptive width.

**Proposition 5.1.** *For every hypergraph  $H$ ,  $\text{adw}(H) \leq \text{fhw}(H)$ .*

*Proof.* Let  $(T, B_{t \in V(T)})$  be a tree decomposition of  $H$  whose  $\rho_H^*$ -width is  $\text{fhw}(H)$ . If  $\phi$  is a fractional independent set, then  $\phi(B_t) \leq \rho_H^*(B_t) \leq \text{fhw}(H)$  for every bag  $B_t$  of the decomposition, i.e.,  $\phi$ -width( $H$ )  $\leq$   $\text{fhw}(H)$ . This is true for every fractional independent set  $\phi$ , hence  $\text{adw}(H) \leq \text{fhw}(H)$ . ■

This implies that if a set of hypergraphs has bounded fractional hypertree width, then it has bounded adaptive width as well. The converse is not true: the main result of this section is a set of hypergraphs with bounded adaptive width (Corollary 5.11) that has unbounded fractional hypertree width (Corollary 5.8).

**Definition 5.2.** The hypergraph  $H(d, c)$  has  $2^{d+1} - 1$  vertices  $v_{i,j}$  ( $0 \leq i \leq d, 0 \leq j < 2^i$ ) and the following edges:

- For every  $0 \leq k < 2^d$ , there is a *large edge*  $E_k$  of size  $d + 1$  that contains  $v_{i, \lfloor k/2^{d-i} \rfloor}$  for every  $0 \leq i \leq d$ .
- For every  $i, j_1, j_2$  with  $|j_1 - j_2| \leq c$ , there is a *small edge*  $\{v_{i,j_1}, v_{i,j_2}\}$ .

We say that vertex  $v_{i,j}$  is on *level  $i$* . We define  $\chi(v_{i,j}) = j2^{d-i}$ . The set  $\mathcal{H}_c$  contains every hypergraph  $H(d, c)$  for  $d \geq 1$ .

**Definition 5.3.** If  $v_{i,j}$  and  $v_{i',j'}$  are covered by the same large edge  $E_k$  and  $i \leq i'$ , then  $v_{i,j}$  is an *ancestor* of  $v_{i',j'}$ ; and  $v_{i',j'}$  is a *descendant* of  $v_{i,j}$ .

**Proposition 5.4.** *If  $v_{i,j}$  is an ancestor of  $v_{i',j'}$ , then  $\chi(v_{i,j}) \leq \chi(v_{i',j'}) < \chi(v_{i,j}) + 2^{d-i}$ .*

*Proof.* The ancestor of  $v_{i',j'}$  on level  $i$  is  $v_{i, \lfloor j'/2^{i'-i} \rfloor}$ . Therefore,

$$\chi(v_{i,j}) = \lfloor j'/2^{i'-i} \rfloor \cdot 2^{d-i} \leq j'/2^{d-i'} = \chi(v_{i',j'})$$

and

$$\chi(v_{i,j}) = \lfloor j'/2^{i'-i} \rfloor \cdot 2^{d-i} > (j'/2^{i'-i} - 1) \cdot 2^{d-i} = j' \cdot 2^{d-i'} - 2^{d-i} = \chi(v_{i',j'}) - 2^{d-i}.$$

■

### 5.1. Lower bound on fractional hypertree width

Fractional hypertree width has various other characterizations that are equivalent up to a constant factor [8]. Here we use the characterization by balanced separators to prove a lower bound on the fractional hypertree width of  $H(d, c)$ .

For a function  $\gamma : E(H) \rightarrow \mathbb{R}^+$ , we define  $\text{weight}(\gamma) := \sum_{E \in E(H)} \gamma(E)$ . For a set  $W \subseteq V(H)$ , we let  $\text{weight}(\gamma|W) = \sum_{e \in E_W} \gamma(e)$ , where  $E_W$  is the set of all edges intersecting  $W$ . For  $\lambda > 0$ , a set  $S \subseteq V(H)$  is a  $\lambda$ -balanced separator for  $\gamma$  if  $\text{weight}(\gamma|C) \leq \lambda \cdot \text{weight}(\gamma)$  for every component  $C$  of  $H \setminus S$ .

**Theorem 5.5** ([8]). *Let  $H$  be a hypergraph and  $\gamma : E(H) \rightarrow \mathbb{R}^+$ . There is a  $\frac{1}{2}$ -balanced separator  $S$  for  $\gamma$  such that  $\rho_H^*(S) \leq \text{fhw}(H)$ .*

Theorem 5.5 can be generalized to  $\lambda$ -separators with arbitrary  $\lambda > 0$  (proof is omitted):

**Corollary 5.6.** *Let  $H$  be a hypergraph and  $\gamma : E(H) \rightarrow \mathbb{R}^+$ . For every  $\lambda > 0$ , there is a  $\lambda$ -balanced separator  $S$  for  $\gamma$  such that  $\rho_H^*(S) \leq 2 \text{fhw}(H)/\lambda$ .*

**Proposition 5.7.** *For every  $c \geq 5$  and  $d > 2 \log_2 c$ ,  $\text{fhw}(H(d, c)) \geq \sqrt{d}/(2c)$ .*

*Proof.* Let  $\gamma$  be a weight function on the edges that assigns 1 to each large edge and 0 to the small edges. We show that every  $\frac{1}{2c}$ -balanced separator of  $H(d, c)$  for  $\gamma$  has fractional cover number at least  $\sqrt{d}/2$ . By Corollary 5.6,  $\text{fhw}(H(d, c)) \geq \sqrt{d}/(8c)$  follows.

Suppose that  $S$  is a  $\frac{1}{2c}$ -balanced separator of  $H(d, c)$  for  $\gamma$ . Observe that on level  $d/2$ , there are at least  $c$  vertices:  $2^{d/2} \geq c$ . We claim that there is a  $d/2 \leq i \leq d$  for which there is no  $0 \leq a_i \leq 2^i - c$  such that  $v_{i,j} \in S$  for every  $a_i \leq j < a_i + c$ . Suppose that there is such an  $a_i$  for every  $d/2 \leq i \leq d$ . Let  $b_i = a_i + c - 1$ . It follows from the definition of  $a_i$  that  $v_{i,a_i}, v_{i,b_i} \in S$  for every  $d/2 \leq i \leq d$ . We claim that the set  $X = \{v_{i,a_i}, v_{i,b_i} : d/2 \leq i \leq d\}$  contains an independent set of size at least  $\sqrt{d}/2$ , contradicting the assumption that the fractional cover number  $\rho^*(S)$  is less than  $\sqrt{d}/2$  (recall that  $\alpha_H(S) \leq \rho_H^*(S)$  holds). First we show that if a large edge  $E_k$  covers  $v_{i,a_i}$  and  $v_{i',a_{i'}}$ , then  $v_{i,b_i}$  and  $v_{i',b_{i'}}$  are independent. Assume without loss of generality that  $i < i'$ . By Prop. 5.4,  $|\chi(v_{i,a_i}) - \chi(v_{i',a_{i'}})| < 2^{d-i}$ . Since  $\chi(v_{i,b_i}) = \chi(v_{i,a_i}) + (c-1)2^{d-i}$  and  $\chi(v_{i',b_{i'}}) = \chi(v_{i',a_{i'}}) + (c-1)2^{d-i'}$ ,

$$\begin{aligned} |\chi(v_{i,b_i}) - \chi(v_{i',b_{i'}})| &> (c-1)2^{d-i} - (c-1)2^{d-i'} - 2^{d-i} \\ &\geq (c-1)2^{d-i} - \frac{c-1}{2} \cdot 2^{d-i} - 2^{d-i} = (c/2 - 3/2)2^{d-i} \geq 2^{d-i}, \end{aligned}$$

if  $c \geq 5$ . Therefore,  $v_{i,b_i}$  and  $v_{i',b_{i'}}$  are independent (Prop. 5.4). Similarly, if a large edge  $E_k$  covers both  $v_{b_j,j}$  and  $v_{b_{j'},j'}$  then  $v_{a_j,j}$  and  $v_{a_{j'},j'}$  are independent.

If  $X$  can be covered with weight less than  $\sqrt{d}/2$ , then there is an edge that covers at least  $|X|/(\sqrt{d}/2) = 2\sqrt{d}$  vertices of  $X$ . Denote by  $Y \subseteq X$  this set of vertices, and let  $Y_a = \{v_{i,a_i} \in Y : d/2 \leq i \leq d\}$  and  $Y_b = \{v_{i,b_i} \in Y : d/2 \leq i \leq d\}$ . Now either  $|Y_a| \geq \sqrt{d}$  or  $|Y_b| \geq \sqrt{d}$ . For each vertex  $v_{i,a_i}$ , we call the vertex  $v_{i,b_i}$  the *pair* of  $v_{i,a_i}$  and vice versa. If  $|Y_a| \geq \sqrt{d}$ , then we have seen that the pairs of the vertices in  $Y_a$  form an independent set of size  $|Y_a|$ , thus  $X$  cannot be covered with weight less than  $\sqrt{d}$ . Similarly, if  $|Y_b| \geq \sqrt{d}$ , then the pairs of the vertices in  $Y_b$  give an independent set of size  $\sqrt{d}$ . This contradicts the assumption that  $S$  can be covered with weight strictly less than  $\sqrt{d}/2$ .

Thus there is a  $d/2 \leq i \leq d$  such that for every  $0 \leq j \leq 2^i - c$ , at least one of  $v_{i,j}, \dots, v_{i,j+c-1}$  is not in  $S$ . It is not difficult to see that the set  $C_i$  of vertices on level  $i$  not in  $S$  is connected and intersects more than  $1/(2c)$  fraction of the large edges. Thus  $\text{weight}(\gamma|C) > \text{weight}(\gamma)/2c$  for the component  $C$  of  $H(d, c) \setminus S$  containing  $C_i$ , contradicting the assumption that  $S$  is a  $\frac{1}{2c}$ -balanced separator for  $\gamma$ . ■

**Corollary 5.8.**  $\mathcal{H}_c$  has unbounded fractional hypertree width for every  $c \geq 5$ .

### 5.2. Upper bound on adaptive width

We use the following lemma to give an upper bound for  $f$ -width (proof is omitted):

**Lemma 5.9.** Let  $H$  be a hypergraph,  $0 < \lambda < 1, w > 0$  constants, and  $f : 2^{V(H)} \rightarrow \mathbb{R}^+$  a function such that  $f(X) \leq f(Y)$  for every  $X \subseteq Y$  and  $f(X \cup Y) \leq f(X) + f(Y)$  for arbitrary  $X, Y$ . Assume that for every subset  $W \subseteq V(H)$  there is a subset  $S \subseteq V(H)$  with  $f(S) \leq w$  such that every component  $C$  of  $H \setminus S$  has  $f(C \cap W) \leq \lambda f(W)$ . Then the  $f$ -width of  $H$  is at most  $2w/(1 - \lambda) + w$ .

To obtain the upper bound on adaptive width, we have to show that the required separator  $S$  exists for every fractional independent set. We say that a set  $S$  is *closed* if the set  $S$  contains every ancestor of every vertex of  $S$ . For future use, we show that even a closed separator exists for  $H(d, c)$ .

**Lemma 5.10.** Let  $\phi$  be a fractional independent set of  $H(d, c)$  and let  $W$  be a subset of vertices. Then there is a closed set  $S$  with  $\phi(S) \leq 4c(c+1)+5$  such that for every component  $C$  of  $H(d, c) \setminus S$  we have  $\phi(C \cap W) \leq 3\phi(W)/4$ .

*Proof.* Let  $M(a, b)$  be the set of vertices  $v_{i,j}$  with  $a \leq \chi(v_{i,j}) < b$ . Let  $x$  and  $y$  be integers such that  $\phi(M(x, x+y) \cap W) \geq \phi(W)/4$  and  $y$  is as small as possible. Let  $d_0 = d - \lceil \log_2 y \rceil$ ; clearly, we have  $y \leq 2^{d-d_0} \leq 2y$ . Let  $A(t) := \{v_{i,j} : \chi(v_{i,j}) \geq t \text{ and } i \geq d_0\}$ . Denote by  $S(t)$  the set of those vertices  $v$  that have a descendant  $v_{i,j}$  with  $\chi(v_{i,j}) < t$  such that  $v_{i,j}$  has a neighbor in  $A(t)$ . We show that  $\phi(S(t_1)) \leq 2c(c+1) + 1$  for some  $x - y < t_1 \leq y$ .

Let  $S_1(t)$  be those vertices of  $S(t)$  that are on level less than  $d_0$  and let  $S_2(t)$  be those vertices that are on level at least  $d_0$ . First we bound  $\phi(S_1(t))$ . Observe that every  $v \in S_1(t)$  has a descendant  $v_{i,j}$  with  $\chi(v_{i,j}) \geq t - c2^{d-d_0}$ : if descendant  $v_{i,j}$  has a neighbor  $u \in A(t)$ , then either  $v_{i,j}$  and  $u$  are connected by a large edge (in this case  $u$  is also a descendant of  $v$ ) or  $v_{i,j}$  and  $u$  are connected by a small edge (in this case  $\chi(v_{i,j}) \geq t - c2^{d-i} \geq t - c2^{d-d_0}$ ). Let  $X$  be the set of vertices  $v_{d_0,j}$  with  $t - c2^{d_0} \leq \chi(v_{d_0,j}) < t$ , we have  $|X| \leq c$ . By the observation above, every  $v \in S_1(t)$  has a descendant in  $X$ . The vertices in  $X$  and the ancestors of  $X$  can be covered by  $|X| \leq c$  large edges. Thus  $\phi(S_1(t)) \leq c$ , as  $S_1(t)$  can be covered with at most  $c$  large edges and  $\phi(E_k) \leq 1$  for every large edge  $E_k$ .

We show that  $\phi(S_2(t))$  is small on average. We claim that

$$\sum_{t=x-y+1}^x \phi(S_2(t)) \leq c \sum_{t=\max\{0, (x-y-c2^{d-d_0})\}}^{\min\{2^d, x+2^{d-d_0}-1\}} \phi(E_t) \leq c(c+1)2^{d-d_0} + y \leq 2c(c+1)y + y.$$

holds, implying that  $\phi(S_2(t)) \leq 2c(c+1) + 1$  for at least one  $t$ . To see the first inequality, observe that  $v_{i,j}$  with  $i \geq d_0$  is in  $S_2(t)$  only if  $t - c2^{d-i} \leq \chi(v_{i,j}) < t$ . Thus such a vertex contributes to the first sum for at most  $c2^{d-i}$  values of  $t$ . However, if  $v_{i,j}$  contributes at all

to the first sum, then it contributes to the second sum for exactly  $2^{d-i}$  values of  $t$ , as every large edge containing  $v_{i,j}$  is counted. Thus  $v_{i,j}$  contributes  $\phi(v_{i,j})$  at most  $c$  times more to the first sum than to the second, which is taken care by the factor  $c$  before the second sum.

Similarly, we can show that there is a value  $x + y \leq t_2 < x + 2y$  such that  $\phi(S_2(t_2)) \leq 2c(c + 1) + 1$ . Denote by  $T(t_1, t_2)$  the vertices of  $M(t_1, t_2)$  on level less than  $d_0$ . We claim that  $\phi(T(t_1, t_2)) \leq 3$ . First,  $T(t_1, t_2)$  can contain at most 3 vertices on each level: if  $v_{i,j}, v_{i',j'} \in T(t_1, t_2)$  and  $j' \geq j + 3$ , then  $|\chi(v_{i,j}) - \chi(v_{i',j'})| \geq 3 \cdot 2^{d-i} > 3 \cdot 2^{d-d_0} \geq 3y \geq t_2 - t_1$ , contradicting the assumption on the  $\chi$ -values. Every  $v_{i,j} \in T(t_1, t_2)$  has a descendant  $v_{i',j'} \in T(t_1, t_2)$  for every  $i < i' < d_0$ , namely  $v_{i',j'}$  with  $j' = j2^{i'-i}$ . Thus by covering the at most 3 vertices of  $T(t_1, t_2)$  on level  $d_0 - 1$  by at most 3 large edges, we can cover  $T(t_1, t_2)$ , and  $\phi(T(t_1, t_2)) \leq 3$  follows.

Define  $S := S(t_1) \cup S(t_2) \cup T(t_1, t_2)$ . Clearly,  $\phi(S) \leq 2(2c(c+1)+1)+3 = 4c(c+1)+5$ . We show that  $S$  separates  $M(t_1, t_2)$  from the rest of the vertices. Suppose that  $v_{i,j}, v_{i',j'} \notin S$  are adjacent vertices such that  $v_{i,j} \in M(t_1, t_2)$  and  $v_{i',j'} \notin M(t_1, t_2)$ . We have  $i \geq d_0$  (otherwise  $v_{i,j} \in T(t_1, t_2)$ ), hence  $v_{i,j} \in A(t_1)$ . If  $\chi(v_{i',j'}) < t_1$ , then  $v_{i',j'} \in S(t_1) \subseteq S$ , a contradiction. Moreover, if  $\chi(v_{i',j'}) > t_2$ , then  $i' \geq d_0$  as  $v_{i,j}$  and  $v_{i',j'}$  are not neighbors if  $\chi(v_{i,j}) < \chi(v_{i',j'})$  and  $i > i'$ . Thus  $v_{i',j'} \in A(t_2)$  and  $v_{i,j} \in S(t_2) \subseteq S$ , a contradiction.

By the definition of  $x$  and  $y$ , we have  $\phi(M(t_1, t_2) \cap W) \geq \phi(M(x, x+y) \cap W) \geq \phi(W)/4$ . To complete the proof that  $\phi(W \cap C) \leq 3\phi(W)/4$  for every component  $C$  of  $H(d, c) \setminus S$ , we show that  $\phi(M(t_1, t_2) \cap W) \leq 3\phi(W)/4$ : as we have seen that every such component  $C$  is fully contained in either  $M(t_1, t_2)$  or  $V \setminus M(t_1, t_2)$ , this means that no component  $C$  can have  $\phi(W \cap C) > 3\phi(W)/4$ . Since  $x - t_1 < y$ , the minimality of  $y$  implies  $\phi(M(t_1, x) \cap W) \leq \phi(W)/4$ . Similarly, it follows from  $t_2 - (x+y) < y$  that  $\phi(M(x+y, t_2) \cap W) \leq \phi(W)/4$ . Now  $\phi(M(t_1, t_2) \cap W) = \phi(M(t_1, x) \cap W) + \phi(M(x, x+y) \cap W) + \phi(M(x+y, t_2) \cap W) \leq \frac{3}{4}\phi(W)$ . ■

By Lemma 5.10, the requirements of Lemma 5.9 hold for  $H(d, c)$  with  $w := 4c(c + 1) + 5$  and  $\lambda := 3/4$ , hence  $\text{adw}(H(d, c)) \leq 9w = 36c(c + 1) + 45$ .

**Corollary 5.11.** *The class  $\mathcal{H}_c$  has bounded adaptive width for every fixed  $c \geq 1$ .*
