Abstract: Semantic wikis have opened an interesting way to mix Web 2.0 advantages with the Semantic Web approach. However, compared to other collaborative tools, wikis do not support all collaborative editing mode such as offline work or multi-synchronous editing. The lack of multi-synchronous supports in wikis is a problematic, especially, when working with semantic wikis. In these systems, it is often important to change multiple pages simultaneous in order to refactor the semantic wiki structure. In this paper, we present a new model of semantic wiki called Multi-Synchronous Semantic Wiki (MS2W). This model extends semantic wikis with multi-synchronous support that allows to create a P2P network of semantic wikis. Semantic wiki pages can be replicated on several semantic servers. The MS2W ensures CCI consistency on these pages relying on the Logoot algorithm.

Key-words: Semantic wikis, Distributed collaborative systems, Multi-synchronous collaboration, Data synchronization

Wikis Sémantiques multi-synchrones

Résumé : Les Wikis sémantiques ont ouvert un chemin intéressant pour combiner les avantages du Web 2.0 avec le Web sémantique. Comparés aux éditeurs collaboratifs existants, les wikis ne supportent pas tous les modes d'édition collaborative tels que le mode d'édition déconnecté et l'édition multi-synchrone. L'absence du mode d'édition multi-synchrone dans les wikis est problématique, tout spécialement dans le cas des wikis sémantiques. Dans ces systèmes, il est souvent important de modifier plusieurs pages simultanément afin de restructurer les wiki sémantiques d'une façon transactionnelle puisque le changement d'une page peut affecter d'autres pages. Dans ce papier, nous proposons un nouveau modèle de wikis sémantiques nommé Wiki Sémantique Multi-Synchrone (MS2W). Ce mode supporte le travail multi-synchrone qui permet la création d'un réseau pair-à-pair de wikis sémantiques. Les pages wikis sémantiques peuvent être répliquées sur plusieurs serveurs wikis sémantiques. Le modèle MS2W proposé assure le respect du modèle de cohérence CCI sur ses pages en se basant sur l'algorithme Logoot.

1 Introduction

Wikis have demonstrated how it is possible to convert a community of strangers into a community of collaborators producing all together valuable contents. Semantic wikis [25, 22, 21, 3] by introducing semantic annotations within wiki pages, have opened an interesting way to mix Web 2.0 advantages with the Semantic Web approach [6].

However, compared to other collaborative tools, wikis do not support all collaborative editing mode such as offline work or multi-synchronous editing [7, 16]. It is not possible to work with a wiki as it is possible to work with popular distributed version control systems (DVCS) [1] such as Git [9] and Mercurial [15].

The lack of multi-synchronous support in wikis is a problematic, especially, when working with semantic wikis. In these systems, it is often important to change multiple pages simultaneous in order to refactor the semantic wiki structure. Without multi-synchronous support all incremental changes will be visible to both end users and semantic request engines. Therefore, they can observe inconsistent states of the wiki as in a database system without transactional support. We can say that existing wikis do not support transactional changes. Moreover, the lack of multi-synchronous support prevents users to work insulated [8] and also prevents semantic wikis to support dataflow oriented workflow.

One approach to solve this problem is to synchronize a network of semantic wikis using distributed version control systems. Unfortunately, DVCS do not support data types used in semantic wikis and do not ensure the CCI consistency model [24] required for distributed collaborative environment.

Another approach is to integrate the DVCS collaboration model into a semantic wikis and manage synchronization of wikis using a CCI preserving algorithm. This can be achieved by deploying a network of semantic wikis. Every node of the network replicates a subset of semantic wiki pages. Any node of the network can be connected to another using a publish/subscribe model. A node that publishes changes just push operations representing these changes in a feed. A node that subscribed to this feed can pull operations at any time and re-execute remote operations locally.

In this paper, we present a new model of semantic wikis called Multi-Synchronous Semantic Wiki (MS2W). This model extends semantic wikis with multi-synchronous support that allows to create a P2P network of semantic wikis based on declarative collaborative community. Semantic wiki pages can be replicated on several semantic servers. The MS2W ensures CCI consistency on these pages relying on the Logoot algorithm [27]. In this paper, we define a MS2W ontology and algorithms. This ontology can be used to compute awareness metrics for working in multi-synchronous environment [17]. Finally, we demonstrate that combining these algorithms with the Logoot algorithm allow to preserve the CCI consistency model.

The paper is organized as follows. Section 2 presents background and related works. Section 3 gives an overview of the muti-synchronous semantic wikis (MS2W) and shows scenarios of new collaboration mode in semantic wikis. Section 4 develops the data model, the algorithms for MS2W and presents the correction of our algorithms. Section 5 presents

the implementation of the MS2W. The last section concludes the paper and points to some directions for future works.

2 Background and Related work

This section gives a brief overview of semantic wikis and shows their drawbacks. Then, it presents the definition and the principals of multi-synchronous collaboration. Finally, it presents the CCI consistency model.

2.1 Semantic Wikis

Semantic wikis such Sematic MediaWiki [12], IkeWiki [22], SweetWiki [4] and Swooki [21] are a new generation of collaborative editing tools, they allow users to add semantic annotations in the wiki pages. These semantic annotations can then be used to find pertinent answers to complex queries. Semantic wikis can be viewed as an efficient way to better structure wikis by providing a means to navigate and answer questions or reason, based on annotations.

Semantic wikis are an extension of wiki systems that preserve the same principles of wikis such as simplicity in creating and editing wikis pages. Semantic wikis embed semantic annotations in the wiki content by using Semantic Web technologies such as RDF and SPARQL. In semantic wikis, users collaborate not only for writing the wiki pages but also for writing semantic annotations. They provide a solution for creating and managing pages and allowing knowledge representation. Traditionally, authoring semantics and creation ontologies has mainly been in the hand of “ontologists” and knowledge management experts. Semantic wikis allow mass collaboration for creating and emerging ontologies. Some existing semantic wikis allows the emergence of the ontology, MediaWiki(SMW) [12] and SweetWiki [4]. Others use the wikis as a collaborative ontologies editors. IkeWiki [22] aims to create an instance of existing ontologies, while OntoWiki [2] is aims the creation of ontology schema .

In a semantic wiki, users add semantic annotations to wiki page text to represent relations and properties on this page. In SMW users choose their own vocabularies to type links. For instance, a link between the wiki pages “France” and “Paris” may be annotated by a user as “capital”.

Content of wiki page of “France”	Content of semantic wiki page of “France”
France is located in [Europe] The capital of France is [Paris]	France is located in [locatedIn::Europe] The capital of France is [hasCapital:: Paris]

These annotations express semantic relationships between wikis pages. Semantic annotations are usually written in a formal syntax so they are processed automatically by machines and they are exploited by semantic queries. For the end-user, a semantic wiki page will appear as a normal wiki page.

In spite of their success, semantic wikis do not support a multi-synchronous work mode. Their current model provides only one copy of a semantic wiki page. The state of a semantic wiki page is always the current visible one on the server, intermediate inconsistent states are always visible. Consequently, transactional changes are not supported neither the isolated work mode nor off-line editing mode.

In previous work, we proposed SWOOKI [21] the first P2P semantic wiki. SWOOKI combines the advantages of P2P wikis and semantic wikis. It is based on an optimistic replication algorithm that ensures the CCI consistency model. It supports the off-line work mode and transactional changes. Users can disconnect their peers, work in isolation and reconnect to the network at any time. The main limitations of SWOOKI are the replication and the collaboration model. SWOOKI adopts a total replication of data, every peer of the network hosts a replica of wiki pages and a replica of the semantic store. Users cannot choose the pages that they want to replicate neither the period of synchronization. Modifications are propagated on page saving. In SWOOKI, the collaborative community is implicit. Users cannot choose to whom propagate modifications. Changes propagation is under the control of system and not the users. All connected peers receive and integrate changes. A disconnected peer will receive the modifications of the others at reconnection thanks to the anti-entropy algorithm.

2.2 Muti-synchronous Collaboration

Dourish wrote [7], *“The notion of multiple, parallel streams of activity, is a natural approach to supporting this familiar pattern of collaborative work. Working activities proceed in parallel (multiple streams of activity), during which time the participants are disconnected (divergence occurs); and periodically their individual efforts will be integrated (synchronization) in order to achieve a consistent state and progress the activity of the group”*.

Multi-synchronous applications are different from synchronous and asynchronous ones by managing multiple streams of activities instead of giving the illusion of one stream. In standard collaborative applications, when a modification is made by one user, it is immediately visible by others. However, in multi-synchronous applications, modifications made by one user are not visible by others. They become visible only when a user validates his modifications (commits his changes). A visible change does not imply immediate integration by other activities streams. Concurrent modifications will be integrated only when users will decide it. Allowing deferred validation of changes and divergence have several important advantages and impacts [18]: Parallelization of activities, privacy, invisibility of partial changes and experimental changes.

Multi-synchronous authoring tools [7, 16] allow simultaneous work in isolation and later integration of the contributions. They are characterized by their abilities to support divergence *i.e* parallel steam of activities on replicated data. SAMS [19] and Distributed Version Control Systems[1] are collaborative systems that support the muti-synchronous collaboration mode.

SAMS [19] is a collaborative environment that allows team members to work in synchronous, asynchronous or mutli-synchronous mode while ensuring the coherence of the

shared data. SAMS uses an operational transformation algorithm to maintain the consistency of the shared data. Although it is independent of shared objects types, SAMS requires the design of transformation functions that depend on the type of the shared object. Designing transformation functions is a hard task and errors prone, Currently, there are no transformation functions designed for semantic wiki pages.

Distributed Version Control Systems[1] such Git manage files and directories. They are not used to track changes in semantic wiki pages. They ensure causal consistency, this implies that concurrent write operations can be seen in a different order on different machines. In this case, if two sites observe 2 write operations in different order then copies on both sites can diverge. DVCS systems are aware of this problem and delegate the problem to external merge algorithms for managing concurrent operations. However, as existing merge algorithms are not intrinsically deterministic, commutative and associative so convergence cannot be ensured in all cases.

2.3 CCI Consistency Model

A distributed collaborative system is composed of unbounded set of peers P . Objects modified by the system are replicated into a set of replicas R (with $0 < |R| \leq |P|$). Every replica has the same role and hosted on one peer. A peer can host replicas of different objects. Peers can enter and leave the network arbitrary. Every peer has a unique comparable identifier. The modifications applied on a replica are eventually delivered and applied on all other replicas. According to [24], the system is correct if it ensures the CCI (Causality, Convergence and Intention Preservation) consistency model.

- **Causality:** This criterion ensures that all operations ordered by a precedence relation, in the sense of the Lamport's *happened-before* relation [13] will be executed in same order on every site.

- **Convergence:** The system converges if all replicas are identical when the system is idle (eventual consistency).

- **Intention and Intention preservation:** The intention of an operation is the effects observed on the state when the operation was generated. The effects of executing an operation at all sites are the same as the intention of the operation. The effect of executing an operation does not change the effects of independent (not causally dependent) operations.

Many algorithms that verify the CCI model have been developed by the Operational Transformation community [24] such as SOCT2, GOTO, COT etc. But only few of them (MOT2 [5]) support the join and leave constraint of P2P network. However, MOT2 algorithm suffers from a high communication complexity [10].

WOOT [20] is the first synchronization algorithm that ensures the CCI consistency and respects the P2P constraints. WOOT is used in WOOKI [26] a peer-to-peer wiki and an modified version of WOOT that takes in consideration semantic data is implemented in SWOOKI [23]. Recently, an optimized version of WOOT called Logoot is published in [27], Logoot ensures convergence and preserves the intentions, if the causality is preserved.

3 Mutli-synchronous Semantic Wiki Approach

Multi-synchronous semantic wikis allow users to build their own cooperation networks. The construction of the collaborative community is declarative, in the sense, every user declares explicitly with whom he would like to cooperate.

Every user can have a multi-synchronous semantic wiki server installed on her machine. She can create and edit her own semantic wiki pages as in a normal semantic wiki system. Later, she can decide to share or not these semantic wiki pages and decide with whom to share.

3.1 Mutli-synchronous Collaboration Model

The replication of data and the communication between servers is made through *channels* (feeds). The channel usage is restricted to few servers with simple security mechanisms that requires no login and complex access control. Capabilities fit perfectly these requirements [14]. The key point is that channels are read-only for consumers and can be hosted on hardware of users.

When a semantic wiki page is updated on a server multi-synchronous semantic wiki, it generates a corresponding operation. This operation is processed in four steps:

1. It is executed immediately against page,
2. it is published to the corresponding *channels*,
3. it is pulled by the authorized servers,
4. it is integrated to their local replica of the page. If needed, the integration process merges this modification with concurrent ones, generated either locally or received from a remote server.

The system is correct if it ensures the CCI (Causality, Convergence and Intention Preservation) consistency model [24].

Multi-synchronous semantic wikis use the Logoot [27] synchronization algorithm to integrate modifications. Logoot ensures the CCI [24] consistency model. More precisely, Logoot ensures convergence and preserves the intentions of operations if the causality of the operations is preserved.

3.2 Collaboration Scenarios

This section presents two scenarios of collaboration in multi-synchronous semantic wikis. In these scenarios, we suppose several professors collaborate together through a semantic wiki to prepare lectures, exercises and exams. Later, they want to make lectures available for students and they want to integrate relevant feedbacks from students.

Scenario 1: Collaboration among professors For simplicity, we suppose there are two professors $prof_1$ and $prof_2$ (see figure 1). Every professor has her own multi-synchronous semantic wiki, $site_1$ for $prof_1$ and $site_2$ for $prof_2$, respectively. The scenario of collaboration is as follows.

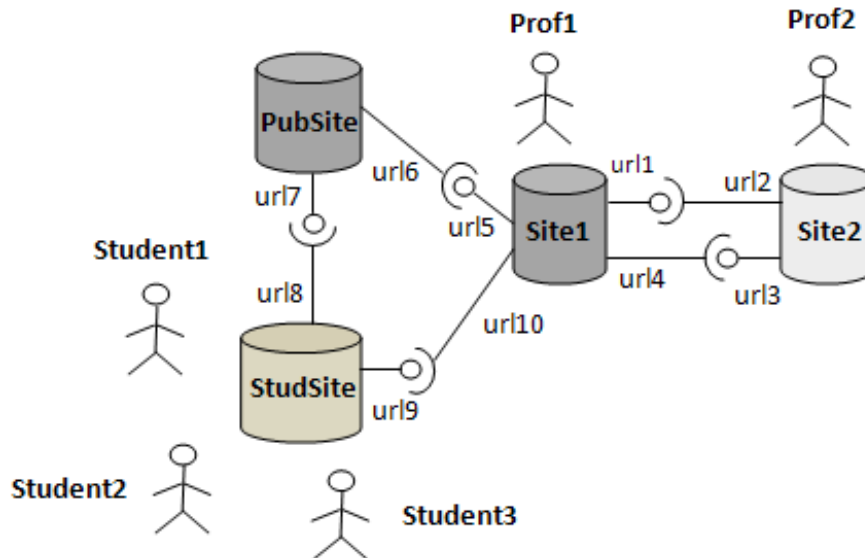

Figure 1: Mutli-synchronous semantic wikis scenario

- Step 1: $prof_1$ edits three semantic wiki pages $lesson_1$, $exercises_1$ and $exam_1$ on her site $site_1$. For instance, the page $lesson_1$ edited by $prof_1$ has three lines:

Introduction:

In "multi-synchronous" work, parties work independently in parallel.
 [Category::Lesson] [forYear:2009]

- Step 2: $prof_1$ wants to publish her modifications on $lesson_1$ to $prof_2$. Therefore, she creates a feed url_1 that contains change set. Finally, she communicates the address of the feed to $prof_2$.
- Step 3: $prof_2$ subscribes to this channel and creates a feed url_2 to pull modifications. The result is a local semantic wiki page $lesson_1$ that has the same content as $lesson_1$ of $prof_1$.
- Step 4: $prof_2$ edits his local copy of the $lesson_1$ page. $lesson_1$ has now five lines:

Introduction:

In "multi-synchronous" work mode, parties work independently in parallel.

[Category::Lesson] [forYear:2009] This mode is based on divergence and synchronization phases. Multiple copies with different views of the data state can exist for the replicated data.

- Step 5: In her turn, $prof_2$ wants to share her modifications on $lesson_1$ with $prof_1$. She creates a feed and publishes his modifications. $prof_1$ subscribes to the feed and pulls the modifications published by $prof_2$ and finally integrates these modifications on her local copy of $lesson_1$. The integration process merges the remote modifications with concurrent ones, if any, generated locally by $prof_1$. The integration process has to ensure the convergence of all copies on $lesson_1$ if all generated operations on $site_1$ and $site_2$ are integrated on both sites.

In the same way, the $prof_1$ and $prof_2$ collaborate for the elaboration of the exercises and exam. The table 1 represents a part of the scenario.

Table 1: Muti-synchronous collaboration scenario

$Site_1$	$Site_2$	Comments
Edit($lesson_1$)		
Edit($exercises_1$)		
Edit($exam_1$)		
Create(f_1, q_1)		create feed to publish modifications on pages in the query q_1 ($lesson_1$)
Push(f_1)		modifications available on f_1
	Subscribe(f_1, f_2)	f_2 is subscribed to f_1
Edit($lesson_1$)	Edit($lesson_1$)	multi-synchronous editing
Push(f_1)		new modifications are available
	Create(f_3, q_2)	create feed to publish modifications

The collaboration process between $prof_1$ and $prof_2$ continues through a sequence of editions followed by pull and push actions on both sites. The advantages of this collaboration model are, on the one hand, there is no need for centralized server to cooperate. On the other hand, every professor works on her or his own copy in isolation, publishes and pulls changes whenever she wants *i.e.* the changes propagation is under the control of the user. This collaboration process is not supported in classical semantic wikis.

Scenario 2: Collaboration among professors and students In this scenario, $prof_1$ want to make $lesson_1$ available for her students while she continues to make corrections and minor modifications on $lesson_1$. In order to provide her students with the courses, $prof_1$ publishes them on a public site $pubSite$ that can be either her proper public wiki site or the site of the university. $pubSite$ is accessible by the students for read only to maintain the

courses consistency. However, $prof_1$ manages to integrate relevant feedbacks from students. The scenario of collaboration is as follows.

- $prof_1$ creates a push feed on her server $site_1$. This channel publishes only the lessons and the exercises without the exams.
- $prof_1$ connects to $pubSite$ and creates a pull feed on the later created push feed then she pulls from it. The result of the pull is the creation of the $lesson_1$ and $exercises_1$ pages on $pubSite_1$ having the same content as in $site_1$. Starting from this point, the $prof_1$ can publish her courses progressively in an easy, safe and satisfied manner.
- Students can have their own multi-synchronous wiki servers, they can pull $lesson_1$ from $pubSite$ and personalize $lesson_1$. They can cooperate directly among students without the professor or they can decide to communicate their modifications to $prof_1$.
- $prof_1$ can pull students' modifications to her private server in case she finds some interesting pages created by the students useful for developing her courses or when some improvements and corrections are made on her courses. She can make these modifications available on the public site.

Professor can make continuous improvement of the lessons and can make continuous integration of the modifications and make only consistent modifications visible. Without multi-synchronous support all incremental changes will be visible to both end users and to semantic request engines. Every participant professor and student want to control the visibility of their modifications and want to control the integration of others' modifications.

4 Mutli-synchronous Semantic Wiki System

This section presents the data model and the algorithms for Mutli-synchronous Semantic Wiki systems. The data model of multi-synchronous semantic wikis (M2SW) is defined an ontology. Therefore, it is possible to querying and reasoning on the model itself. For instance, it is possible queries like: “find all unpublished changes”, “find all published changes on a given channel”, “find unpublished change set of a given semantic wiki page”, etc.

4.1 MS2W Ontology

The data model of multi-synchronous semantic wikis (M2SW) is defined as an extension of existing ontologies of semantic wikis [4]. In this section, we present the M2SW ontology and detail only its new concepts and their properties.

- **WikiSite** : this concept corresponds to a semantic wiki server. A site has the following properties:
 - $siteID$: this attribute contains the *URL* of the site.

Figure 2: Mutli-synchronous ontology

- *logicalClock* : this attribute has a numeric value. Every semantic wiki server maintains a logical clock, this clock is used to identify patches and operations in a unique way in the whole network.
- *hasPush* : the range of this property is push feed. A wiki site has several push feeds.
- *hasPull* : the range of this property is pull feed. A wiki site has several pull feeds.
- *hasPage* : the range of this property is a semantic wiki page. A wiki site has several pages.

- **Document** : a document can be an image, an audio or a video file or any type of file that can be uploaded in a wiki page.
- **SemanticWikiPage**: this concept corresponds to a normal semantic wiki page. It has the following properties:
 - *pageID* : this attribute contains the *URL* of the page.
 - *hasContent* the range of this property is a String, it contains text and the semantic data embedded in the semantic wiki page.
 - *head* : this property points to the *last patch* applied to the page.
- **Operation** : represents a change in a line of a wiki page. In our model, there are two editing operations : *insert* and *delete*. An update is considered as a delete of old value followed by an insert of a new value. An operation has the following properties:
 - *operationID*: this attribute contains the unique identifier of the operation. *operationID* is calculated by: $operationID = \text{concat}(Site.siteID, Site.logicalClock ++)$, the *concat* function concatenates two strings.
 - *opType*: this attribute contains the type of the operation, it can be either an *insert* or a *delete*.
 - *positionID*: denotes the position of the line in the wiki page. This identifier is calculated by the *Logoot* algorithm[27].
 - *lineContent*: is a string representing text and the semantic data embedded in the line.
- **Patch** : a patch is a set of operations. A patch is calculated during the save of the modified semantic wiki page using the Logoot algorithm. A patch has the following properties:
 - *patchID*: is a unique identifier of the patch. Its value is calculated by : $patchID = \text{concat}(Site.siteID, Site.logicalClock ++)$
 - *onPage*: the range of this property is the page where the patch was applied.
 - *hasOperation*: this property points to the operations generated during the save of the page.
 - *previous*: points to the precedent patch.
- **ChangeSet** : a change set contains a set of patches. This concept is important in order to support transactional changes. It allows to regroup patches generated on multiple semantic wiki pages. Therefore, it is possible to push modifications on multiple pages. *ChangeSet* has the following properties:
 - *changSetID*: is a unique identifier of a change set. Its value is calculated as : $changSetID = \text{concat}(Site.siteID, Site.logicalClock ++)$

- *hasPatch* property points to the patches generated since the last push.
 - *previousChangeSet*: points to the precedent change set.
 - *inPushFeed*: the range of this property is a *PushFeed*. This property indicates the *PushFeed* that publishes a *ChangeSet*.
 - *inPullFeed*: the range of this property is a *PullFeed*. This property indicates the *PullFeed* that pulls a *ChangeSet*.
- **PushFeed** : this concept is used to publish changes of a *WikiSite*. It is a special semantic wiki page. It inherits the properties of the *SemanticWikiPage* concept and defines its own properties:
 - *hasPushHead* : this property points to the *last* published *changeSet*.
 - *hasSemanticQuery*: this property contains a semantic query. This query determines the content of the push feed. For instance, the query can be “find all Lessons”, this will return all the pages in the class (category) Lessons. To answer *hasSemanticQuery*, reasoning and querying capabilities of semantic wikis are used.
 - **Pull Feed** : this concept is used to pull changes from a remote *WikiSite*. A pull feed is related to one push feed. In the sense that it is impossible to pull unpublished data. A pull feed is also a special semantic wiki page. It inherits the properties of the *Semantic Wiki Page* concepts and defines its own properties:
 - *hasPullHead*: this property points to the last pulled change set pulled.
 - *relatedPushFeed*: this property relates a pull feed to the *URL* of its associated push feed.

We can use the *MS2W* ontology to query and reason on the patches, ChangeSet, PushFeed, etc. For instance, we can find published patches on a push feed:

$$Published \equiv \exists(hasPatch^{-1}).\exists(inPushFeed^{-1}).PushFeed$$

The unpublished patches is defined by:

$$unPublished \equiv Patch \sqcap \neg(\exists(hasPatch^{-1}).\exists(inPushFeed^{-1}).PushFeed)$$

4.2 Algorithms

As any semantic wiki server, a multi-synchronous semantic server defines a *Save* operation which describes what happens when a semantic wiki page is saved. In addition, we define special operations : *Create Push*, *Push*, *Create Pull*, *Pull* and *Integrate* for the multi-synchronous semantic wiki. We use the Logoot [27] algorithm for the generation and the integration of the *insert* and *delete* operations.

In the following, we will detail these operations for a semantic wiki server called *site*.

Save Operation During the saving a wiki page, the *Logoot* algorithm computes the difference between the saved and the previous version of the page and generates a patch.

```

On Save(page : String, page:String) :-
  Patch(pid=concat(site.siteID, site . logicalClock + +))
  foreach op ∈ Logoot(page, page) do
    Operation(opid=concat(site.siteID, site . logicalClock+ +))
    hasOperation(pid,opid)
  endfor;
  previous(pid,page.head)
  head(page,pid)
  onPage(pid,page)

```

A *patch* is the set of delete and insert operations on the page ($Op = (opType, operationID, positionID, lineContent)$). The *Logoot* algorithm calculates the *positionID*, *lineContent* and the *opType* of the operation. These operations are integrated locally and then eventually published on feed patches. The *Save* operation instantiates the *Patch* concept of the M2SW ontology. For instance, the figure 3 represents the patch associated to the page $lesson_1$ the site $site_1$ of the collaboration scenario represented in the section 3.2. The number in the right bottom box in the *wikiSite1* of the figure indicates the value of the logical clock of the site.

Figure 3: *WikiSite1* state after saving the $lesson_1$ page

CreatePushFeed Operation The communication between multi-synchronouns semantic wiki servers is made through feeds. The *CreatePushFeed* operation allows the creation of a push feed. A push feed is a special semantic wiki page that contains a query that specifies the pushed data.

```

on CreatePushFeed(name : String, request:String):-
  PushFeed(name)
  hasSemanticQuery(name,request)
  hasPush(site,name)
  call Push(name)

```

A push feed is used to publish changes of a wiki server. Therefore, authorized sites can access the published data. *CreatePushFeed* operation calls the *Push* operation.

Push Operation The *Push* operation creates a change set corresponding to the pages returned by the semantic query and adds it to the push feed. First, it executes the semantic query, the patches of the pages are extracted. These patches are added to the change set if they have not been published on this push feed yet.

```

On Push(name:String):-
  ChangeSet(csid=concat(site.siteID,site.logicalClock++))
  inPushFeed(csid, name)
  let published ← { ∃x ∃y ∧ inPushFeed(y,name) ∧ hasPatch(y,x) }
  let patches ← { ∃x ∀p ∈ execQuery(name.hasSemanticQuery) ∧ onPage(x,p) }
  foreach patch ∈ {patches - published}
    hasPatch(csid, patch)
  endfor
  previousChangeSet(csid, name.hasPushHead)
  hasPushHead(name,csid)

```

The push feed creation and the pull of the *lesson₁* page on the *WikiSite₁* in the scenario presented in the section 3.2 is shown in the figure 4. It instantiates a *PullFeed* and a *changeSet* concepts with their corresponding properties.

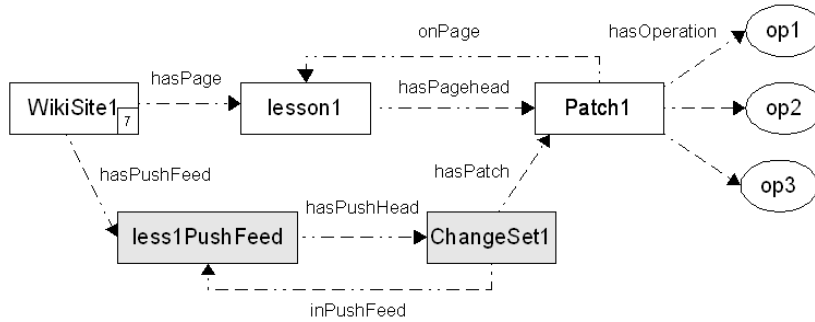

Figure 4: A push feed is created and the page *lesson₁* is pushed

CreatePullFeed Operation As the replication of data and the communication between multi-synchronous semantic wiki servers are made through feeds, pull feeds are created to pull changes from push feeds on remote peers to the local peer. A pull feed is related to a push feed. In the sense that it is impossible to pull unpublished data.

```

On CreatePull(name:String, url:URL):-
  PullFeed(name);

```

```
relatedPushFeed(name,url);
call Pull(name);
```

Pull Operation This operation fetches for published change sets that have not pulled yet. It adds these change sets to the pull feed and integrate them to the concerned pages on the pulled site.

```
On Pull(name:String):-
  while ((cs ← get(name.headPullFeed, name.relatedPushFeed) ≠ null)
    inPullFeed(cs,name)
    call Integrate(cs)
    hasPullHead(name,cs)
  endwhile
```

get operation The *get* function allows to retrieve a ChangeSet.

```
On ChangeSet get(cs : ChangeSetId , url):-
  if ∃x previousChangeSet(cs,x) return x
  else return null;
```

Integration operation The integration of a change set is processed as follows. First all the patches of the change set are extracted. Every operation in the patch is integrated in the corresponding semantic wiki page thanks to the [27] algorithm.

```
Integrate(cs:ChangeSet):-
  foreach patch ∈ cs
  previous(patch, patch.onPage.head)
  head(patch.onPage,patch)
  foreach op ∈ hasOperation.patch
  call logootIntegrate(op);
  endforeach
endforeach
```

The creation of a pull feed on the *WikiSite2* and the pull of the *lesson₁* page as it was published in the push feed of *WikiSite1* are given in the figure 5. Different instances are created starting from the pull feed, followed by the change set and the copy of the patch and its operations. Since the patch concerns a wiki page that does not exist, an instance of the wiki page is created where the patch is applied.

4.3 Correction model

A site always respects the causality of its own operations since it generates these operations alone, so these operations placed in the push feed are causal.

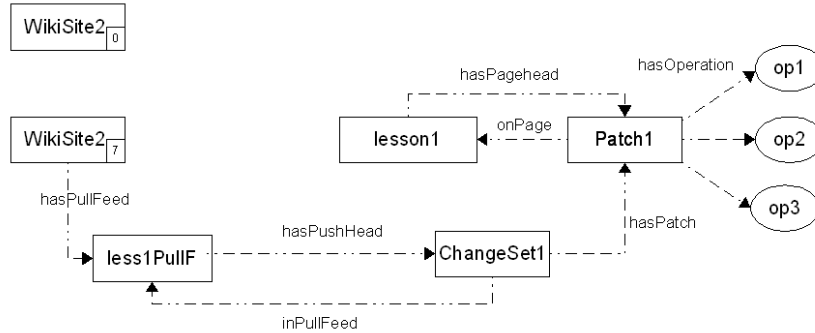

Figure 5: A pull feed is created and the page $lesson_1$ is copied from WikiSite1

In the following, we take an hypothesis that a site S pulls from N sites that ensure the causality and we want to prove that the site itself ensures the causality.

We will prove that the site S can not violate the causality through the contradiction proof. Let consider that the site S violates the causality i.e. in the content of the push feed of that site there is an operation op_2 that depends causally (Lamport dependence) on an operation op_1 and op_2 is placed before op_1 in that feed.

The operations in a push feed has two different sources either they are local generated by the site itself or the site had received from other sites. Let study both cases:

local operations: the local operations always respect the causality, so a site is not going to violate the causality.

remote operations: In order to get the operation op_2 placed at the position N in the push feed of site S , S must pull i.e. copy all the operations that precedes op_2 . Getting op_2 without having op_1 means that op_1 was not among the $N - 1$ operations that precedes op_2 in the push feed which violates the hypothesis that the site S pulls only from N sites that respect the causality.

Consequently, it is not possible to find op_2 before op_1 . In conclusion, a site always respects the causality alone. If this site pulls from N sites that ensure the causality, it ensures the causality itself. In recurrence, all site ensure the causality for any N , where N is an integer. Hence, our algorithm ensures the causality for all the sites in the network.

(Convergence, Intention).

Our algorithm is based on Logoot [27] algorithm for the generation and the integration of the operations. It is proved in [27], that the *Logoot* algorithm ensures the convergence and preserves the intentions, if the causality is preserved. Since our algorithms ensure the causality between the operations (theorem ??), hence it ensures also the convergence and preserves the intentions.

The screenshot shows the 'special' namespace 'P2P Administration' page. It features a navigation sidebar on the left with links like 'Main Page', 'Community portal', and 'Current events'. The main content area is divided into two sections: 'PULL' and 'PUSH', each with a table of site statistics.

Figure 6: MS2W Administration page

5 Implementation

We are currently implementing the MS2W model as an extension of Semantic MediaWiki [11]. Feeds, ChangeSets and Patches are represented as special semantic wiki pages. They stored in a special namespace to prevent user modification. The Logoot algorithm has been implemented in PHP and integrated in Mediawiki relying on the hook mechanism.

The push, pull, createPush and createPull operations are available in special administration pages of MediaWiki as shown in figure 6. Some basic information about the status of different pages are realized using Semantic queries over MS2W ontology.

6 Conclusion and future work

In this paper, we propose a new model of semantic wikis called Multi-Synchronous Semantic Wiki (MS2W). MS2W extends a semantic wiki with multi-synchronous capabilities. Multi-synchronous semantic wikis allow users to build their own cooperation networks. The construction of the collaborative community is declarative, in the sense, every user declares

explicitly with whom he would like to cooperate. The replication of the wiki pages on semantic wikis servers and the synchronization periods are variant and under the control of the users.

The MS2W model enhances the existing semantic wikis by supporting transactional changes and the off-line work mode. Hence, multiple dataflow oriented workflows can be supported. On the other hand, the model takes natural advantages of a P2P network i.e. faults-tolerance, better scalability, infrastructure cost sharing and better performance.

In the paper, we develop an ontology for MS2W. Each ontological element in this wiki is exploitable, consequently advanced reasoning and querying capabilities are provided. We develop also a set of algorithms for the creation and the replication of semantic wiki pages and for the propagation and the synchronization of changes between the peers. The MS2W algorithm ensures the CCI consistency on the pages.

We are currently implementing the MS2W model as an extension of Semantic MediaWiki [11]. As future works, we intend to extend the proposed ontology to cover the users and the semantic annotations in the pages in order to instantiate all kinds of processes. In addition, we want to support the MS2W with two crucial features: (1) an undo mechanism to facilitate the undo of undesired merge results, (2) an advanced mechanism for divergence metrics based on querying the semantic annotations.
