1 Grooming

Jean-Claude Bermond and David Coudert

1.1 Definitions and Examples

1.1 Remark Traffic grooming in networks refers to group low rate traffic into higher speed streams (containers) so as to minimize the equipment cost [11, 7, 13, 12, 8, 9]. There are many variants according to the type of network considered, the constraints used and the parameters one wants to optimize which give rise to a lot of interesting design problems (graph decompositions).

To fix ideas, suppose that we have an optical network represented by a directed graph G (in many cases a symmetric one) on n vertices, for example a unidirectional ring $\vec{C}_n$ or a bidirectional ring C_n^*. We are given also a traffic matrix, that is a family of connection requests represented by a multi-digraph I (the number of arcs from i to j corresponding to the number of requests from i to j). An interesting case is when there is exactly one request from i to j; then $I = K_n^*$. Satisfying a request from i to j consists in finding a route (dipath) in G and assigning it a wavelength. The grooming factor, g, means that a request uses only $1/g$ of the bandwidth available on a wavelength along its route. Said otherwise, for each arc e of G and for each wavelength w, there are at most g dipaths with wavelength w which contain the arc e.

During the 90's, a lot of research has concentrated in minimizing the number of wavelengths used in the network. In the mean time, the bandwidth of each wavelength (> 10 Gbit/s), the number of wavelengths per fiber (> 100) and the number of fibers per cable (> 100) have exploded, thus reporting the operational cost of a wavelength into the terminal equipment cost: filters, optical cross-connect, add/drop multiplexer (ADM),.... For example, in a node of an optical network we place an ADM only for those wavelengths carrying a request which has to be added or dropped in this node. So nowadays the objective is to minimize the total number of ADMs in the network, which is a challenging issue.

1.2 Definition [5] Grooming problem: Given a digraph G (network), a digraph I (set of requests) and a grooming factor g, find for each arc $r \in I$ a path $P(r)$ in G, and a partition of the arcs of I into subgraphs I_w, $1 \le w \le W$, such that $\forall e \in E(G)$, $\mathrm{load}(I_w, e) = |\{P(r); r \in E(I_w); e \in P(r)\}| \le g$. The objective is to minimize $\sum_{w=1}^{W} |V(I_w)|$, and this minimum is denoted by $A(G, I, g)$.

1.3 Definition TT_n is a transitive tournament on n vertices, that is the digraph with arcs $\{(i,j) \mid 1 \le i < j \le n\}$. We denote $\{a,b,c\}$ the TT_3 with arcs $\{a,b\}$, $\{b,c\}$, and $\{a,c\}$.

1.4 Remark When $G = P_n^*$, the shortest path from i to j is unique, and we can split the requests into two classes, those with $i < j$ and those with $i > j$. Therefore the grooming problem for P_n^* can be reduced to two distinct problems on $\vec{P}_n$. In particular we have $A(P_n^*, K_n^*, g) = 2A(\vec{P}_n, TT_n, g)$.

1.5 Example $A(\vec{P}_7, TT_7, 2) = 20$, and the partition consists of 6 subgraphs, the 5 TT_5 {2,4,5}, {3,4,6}, {1,5,6}, {2,6,7}, and {1,4,7}, plus the union of two TT_3 {1,2,3}+{3,5,7}.

1.6 Theorem [1] When n is odd, $A(\vec{P}_n, TT_n, 2) = \lceil (11n^2 - 8n - 3)/24 \rceil$; When n is even, $A(\vec{P}_n, K_n, 2) = (11n^2 - 4n)/24 + \varepsilon(n)$, where $\varepsilon(n) = 1/2$ when $n \equiv 2, 6 \pmod{12}$, $\varepsilon(n) = 1/3$ when $n \equiv 4 \pmod{12}$, $\varepsilon(n) = 5/6$ when $n \equiv 10 \pmod{12}$, and $\varepsilon(n) = 0$ when $n \equiv 0, 8 \pmod{12}$.

1.7 Remark In a unidirectional cycle $\vec{C}_n$, the path from i to j is unique. Wlog we can assign the same wavelength to the two requests (i, j) and (j, i), then the two associated paths contain each arc of $\vec{C}_n$. Therefore the load condition becomes $|E(I_w)| \leq g$ and the grooming problem becomes:

1.8 Definition [5] Grooming problem for $G = \vec{C}_n$: given n and g, find a partition of I into subgraphs B_w, $1 \leq i \leq W$, such that $|E(B_w)| \leq g$, which minimizes $\sum_{w=1}^{W} |V(B_w)|$. The minimum value is $A(\vec{C}_n, I, g)$.

1.9 Remark The partition of Definition 1.2 is obtained by associating to each B_w of the partition of Definition 1.8 its symmetric digraph B_w^* and letting $I_w = B_w^*$.

1.10 Example $A(\vec{C}_4, K_4^*, 3) = 7$, using a partition of K_4 consisting of the K_3 $\{1, 2, 3\}$ and the $K_{1,3}$ with edges $\{1, 4\}$, $\{2, 4\}$, and $\{3, 4\}$. $A(\vec{C}_7, K_7^*, 3) = 21$ using a (7,3,1) design (steiner triple system) and $A(\vec{C}_{13}, K_{13}^*, 6) = 52$ using a (13,4,1) design.

1.11 Theorem [2] $A(\vec{C}_n, K_n^*, 3) = n(n-1)/2 + \varepsilon_3(n)$, where $\varepsilon_3(n) = 0$ when $n \equiv 1, 3 \pmod{6}$, $\varepsilon_3(n) = 2$ when $n \equiv 5 \pmod{6}$, $\varepsilon_3(n) = \lceil n/4 \rceil + 1$ when $n \equiv 8 \pmod{12}$, and $\varepsilon_3(n) = \lceil n/4 \rceil$ otherwise.

1.12 Theorem [10] $A(\vec{C}_n, K_n^*, 4) = n(n-1)/2$.

1.13 Theorem [4] $A(\vec{C}_n, K_n^*, 5) = 4 \lfloor n(n-1)/10 \rfloor + \varepsilon_5(n)$, where $\varepsilon_5(n) = 0$ when $n \equiv 0, 1 \pmod{5}$, $n \neq 5$, $\varepsilon_5(5) = 1$, $\varepsilon_5(n) = 2$ when $n \equiv 2, 4 \pmod{5}$, $n \neq 7$, $\varepsilon_5(7) = 3$, $\varepsilon_5(n) = 3$ when $n \equiv 3 \pmod{5}$, $n \neq 8$, and $\varepsilon_5(8) = 4$.

1.14 Theorem [3]

When $n \equiv 0 \pmod{3}$, then $A(\vec{C}_n, K_n^*, 6) = \lceil n(3n-1)/9 \rceil + \varepsilon_6(n)$, where $\varepsilon_6(n) = 1$ when $n \equiv 18, 27 \pmod{36}$, and $\varepsilon_6(n) = 0$ otherwise, except for $n \in \{9, 12\}$ and some possible exceptions when $n \leq 2580$.

When $n \equiv 1 \pmod{3}$, $A(\vec{C}_n, K_n^*, 6) = \lceil n(n-1)/3 \rceil + \varepsilon_6(n)$, where $\varepsilon_6(n) = 2$ when $n \equiv 7, 10 \pmod{12}$, and 0 otherwise, except for $A(\vec{C}_7, K_7^*, 6) = 17$, $A(\vec{C}_{10}, K_{10}^*, 6) = 34$, and $A(\vec{C}_{19}, K_{19}^*, 6) = 119$.

When $n \equiv 2 \pmod{3}$, then $A(\vec{C}_n, K_n^*, 6) = (n^2 + 2)/3$, except possibly for $n = 17$.

1.15 Remark In another grooming problem (see [6]), the requests can be routed via different pipes. Each pipe contains at most g requests, and the objective is to minimize the total number of pipes (as equipments are placed only at the terminal nodes of the pipe). Thus, given a digraph I (requests) and a grooming factor g, the problem consists in finding a virtual multi-digraph H and, for each arc $r \in I$, a path $P(r)$ in H such that $\forall e \in E(H)$, $\text{load}(I, e) \leq g$. The objective is to minimize $|E(H)|$, and the minimum is denoted by $T(I, g)$.

1.16 Example When $I = K_4^*$ and $C = 2$, then $H = C_4^*$. Requests $(i, i+1)$ (resp. $(i, i-1)$) are routed via arc $(i, i+1)$ (resp. $(i, i-1)$), requests $(1, 3)$ and $(3, 1)$ are routed clockwise, and $(2, 4)$ and $(4, 2)$ counterclockwise.

1.17 Remark For $C = 2$ the problem can be reduced to a partition of K_n^* or $(K_n - e)^*$ in TT_3 (See Directed Design or Mendelsohn's Designs). For $C = 3$ the result follows from the existence of a $PBD(n, \{3, 4, 5\})$ for $n \neq 6, 8$ (see chapter PBD).

1.18 Theorem [6] $T(K_n^*, 2) = \lceil 2n(n-1)/3 \rceil$ and $T(K_n^*, 3) = n(n-1)/2$.
