O rozboru jednoho makra (tutoriál)

Denis Roegel

Abstrakt

V článku dopodrobna rozebíráme makro naprogramované v TEXu, které vypočítá a vypíše prvních n prvočísel. To nám dává prostor k poukázání na některé technické detaily, které jsou častokrát začátečníky přehlíženy. Redakce navíc přidala shrnutí příkazů Plain TEXu jako přílohu tohoto článku.

Klíčová slova: Plain TEX, prvočísla.

doi: 10.5300/2010-1-2/68

This article is dedicated to Chrystel Barraband for whom the first version was written in 1993.

Introduction

A TEX macro can be seen as the definition of a command by other commands. Both the definition of a command and the way arguments are passed obey rules which are both precise and simple, but which are often overlooked, though indispensable to a good understanding of TEX.

Moreover, the call of a TEX macro is a very different process from what happens in classical languages. It is similar to a macro call in the C preprocessor and it is hard to imagine programming with such a language! A macro call merely entails a replacement or a substitution, but it can also call other macros, including itself, which allows recursion.

Computing prime numbers

We will focus on the computation of prime numbers. $n > 1$ is prime if n is divisible only by itself and 1. If n is odd, it is sufficient to divide n by $3, 5, 7, \ldots, p \leq \lfloor\sqrt{n}\rfloor$. For, if n can be divided by $p > \lfloor\sqrt{n}\rfloor$, then n can also be divided by $q < \lfloor\sqrt{n}\rfloor$. The divisors p will be tried until $p^2 > n$.

Macros

The following example, from *The TEXbook* [1], is of an advanced level but will allow us to go straight to the heart of the matter. The macro `\primes` makes it

*Previously published in *TUGboat* **22**:1/2 (March/June 2001), pp. 78–82; translation by the author from the original in *Les Cahiers GUTenberg* number 31, December 1998, pp. 19–27.

possible to determine the first n prime numbers, starting with 2. For instance, `\primes{30}` returns the first 30 prime numbers. Here are all the definitions.

We will then analyze them in detail:

```
\newif\ifprime \newif\ifunknown
\newcount\n \newcount\p
\newcount\d \newcount\a
\def\primes#1{2,~3% assume that #1>2
  \n=#1 \advance\n by-2 % n more to go
  \p=5 % odd primes starting with p
  \loop\ifnum\n>0 \printifprime
       \advance\p by2 \repeat}
\def\printp{, % invoked if p is prime
  \ifnum\n=1 and~\fi
  \number\p \advance\n by -1 }
\def\printifprime{\testprimality
                  \ifprime\printp\fi}
\def\testprimality{{\d=3 \global\primetrue
  \loop\trialdivision
     \ifunknown\advance\d by2 \repeat}}
\def\trialdivision{\a=\p \divide\a by\d
  \ifnum\a>\d \unknowntrue
  \else\unknownfalse\fi
  \multiply\a by\d
  \ifnum\a=\p \global\primefalse
              \unknownfalse\fi}
```

Declarations

First, we declare two booleans, or more precisely two tests.

`\newif\ifprime`

`\ifprime` is equivalent to `\iftrue` if "`prime`" is true. This boolean will make it possible to see if a number must be printed; thus, in `\printifprime`, the expression `\ifprime\printp\fi` means that if `\ifprime` is evaluated to `\iftrue`, then `\printp` (that is, the macro that will print the number of interest to us, namely `\p`) will be executed, otherwise nothing will happen.

`\newif\ifunknown`

"`unknown`" will be true if we are not yet sure whether `\p` is composed or not. Neither is known. Initially, "`unknown`" is thus true and the `\ifunknown` test succeeds. If "`unknown`" is false, we have knowledge about `\p`'s primality, that is, we know if `\p` is prime or not.

Next, we define a few integer variables useful in what follows:

- `\newcount\n`
  `\n` is the number of prime numbers that remain to be printed.
- `\newcount\p`
  `\p` is the current number for which primality is tested.
- `\newcount\d`
  `\d` is a variable containing the sequence of trials of divisors of `\p`.
- `\newcount\a`
  `\a` is an auxiliary variable.

Main macro

The main macro is `\primes`. It takes an argument. When the macro is defined, this argument has the name `#1`. If there were a second argument, it would be `#2`, etc. (It is not possible to have — directly — more than nine arguments; indirectly however, one can have as many arguments as one wants, including a variable number, which could for instance be a function of one of the arguments.)

```
\def\primes#1{2,~3%
  \n=#1 \advance\n by-2 %
  \p=5 %
  \loop\ifnum\n>0 \printifprime
      \advance\p by2 \repeat}
```

When the `\primes` macro is called, for instance with 30, `\primes{30}` is replaced by the body of `\primes` (that is, the group between braces which follows the list of `\primes`' formal arguments), in which `#1` is replaced by the two characters 3 and 0. `\primes{30}` hence becomes (we have removed spaces at the beginning of the lines, because they are ignored by TEX):

```
2,~3%
\n=30 \advance\n by-2 %
\p=5 %
\loop\ifnum\n>0 \printifprime
    \advance\p by2 \repeat
```

What happens now? We print "`2,~3`", that is, 2 followed by a comma, followed by an unbreakable space (i.e., the line will *in no case* be split after the comma); then 30 is assigned to `\n`. Immediately, 2 is subtracted from `\n`, and `\n` then contains the number of primes that remain to be printed. To keep it simple, we have assumed that at least the three first primes must be displayed. Therefore, we are sure that `\n` is at least equal to 1. This is also why it was possible to put a comma between 2 and 3, because we know that 3 is not the last number to be printed. We want the last number printed to be preceded by "`and`". Hence, when

we ask `\primes{3}`, we want to obtain "`2, 3, and 5`". It should also be noticed that the "`%`" after "`3`" is essential to prevent insertion of a spurious space. "`3`" will be followed by a comma when `\printp` is called. The "`%`" after the second and third lines are not really needed since TEX gobbles all spaces after explicit numbers; these "`%`" signs appear only as remnants of comments.

We said that `\p` is the current number whose primality must be tested. We must therefore initialize `\p` to 5, since it is the first odd number after 3 (which we don't bother to check if it is prime or not).

The body of `\primes{30}` ends with a loop:

```
\loop\ifnum\n>0 \printifprime
    \advance\p by2 \repeat
```

It is a `\loop`/`\repeat` loop. In general, these loops have the form

```
\loop A text \if...   B text \repeat
```

This loop executes as follows: it starts with `\loop`, the A text is executed, then the `\if...` test. If this test succeeds, the B text is executed, then `\repeat` makes us return to `\loop`. If the test fails, the loop is over.

Hence, in the case of `\primes{30}`, it amounts to execute

```
\printifprime\advance\p by2
```

as long as `\n` is strictly positive, that is, as long as prime numbers remain to be printed. In order for this to produce the expected result, it is of course necessary to decrement the value of `\n`. This is done every time a number is printed with the call to `\printifprime`.

As a consequence, if at least one number remains to be printed, `\printifprime` will be called and will print `\p` if `\p` is prime. Whatever the result, we pass then to the next odd number with `\advance\p by2`.

Printing

The prime numbers are printed with `\printp`:

```
\def\printp{, %
    \ifnum\n=1 and~\fi
    \number\p \advance\n by -1 }
```

This macro is called only when `\p` is prime (see its call in `\printifprime`). In any case, this macro has no arguments and gets expanded into

```
, %
\ifnum\n=1 and~\fi
\number\p \advance\n by -1
```

that is a comma and a space, followed by "`and `" if `\n` equals 1 (in the case where the number to be printed is the last one), followed by `\p` (the `\number` function is analogous to `\the` and converts a variable into a sequence of printable characters);

finally, \n is decremented by 1, as announced, and this allows a normal unfolding of the \loop...\repeat loop in the \primes macro.

The macro \printifprime is called by \primes. It calls the function computing the primality of \p and this determines if \p must be printed or not.

```
\def\printifprime{\testprimality
                  \ifprime\printp\fi}
```

As one can guess, the \testprimality macro sets the "prime" boolean to "true" or "false," or if one prefers, it makes the \ifprime test succeed or fail.

Primality test

The macro testing \p's primality uses the classical algorithm where divisions are tried by numbers smaller than \p's square root.

```
\def\testprimality{{\d=3 \global\primetrue
  \loop\trialdivision
    \ifunknown\advance\d by2 \repeat}}
```

This macro is more complex because it involves an additional "group," shown here by the braces. Therefore, when \testprimality is expanded, we are left with

```
{\d=3 \global\primetrue
 \loop\trialdivision
   \ifunknown\advance\d by2 \repeat}
```

meaning that what happens between the braces will be — when not otherwise specified — local to that group. This was not the case in the expansions seen previously.

Let us first ignore the group. What are we doing? 3 is first assigned to \d where \d is the divisor being tested. We will test 3, 5, 7, etc., in succession, and this will go on as long as it is not known for certain whether \p is prime or not. As soon as we know if \p is prime or composed, the "unknown" boolean will become false and the \ifunknown test will fail.

Now, let us look at this again: we start with \d=3; the default is to consider \p prime, hence the "true" value is given to the "prime" boolean. This is normally done with

```
\primetrue
```

but in our case, it would not be sufficient. Indeed, at the end of

```
{\d=3 \primetrue
 \loop\trialdivision
   \ifunknown\advance\d by2 \repeat}
```

all variables take again their former value, because the assignments are *local* to the group. But the "`prime`" boolean is used when the `\ifprime...` test is being done in `\printifprime`, which is called after `\testprimality`. The group must therefore be *transcended* and the assignment is coerced to be global. This is obtained with

```
\global\primetrue
```

The remainder is then obvious: an attempt is made to divide `\p` by `\d`, and this is the purpose of `\trialdivision`. If nothing more has been discovered, that is, if "`unknown`" is still "`true`", the value of the trial divisor is set to the next value with `\advance\d by2`. Sooner or later this process stops, as shown by the `\trialdivision` definition.

The additional group in `\testprimality` can now be explained. If the group is not introduced, the expansion of `\primes{30}` leads to

```
...
\loop\ifnum\n>0 \printifprime
  \advance\p by2 \repeat
```

Plain TEX defines `\loop` as follows:

```
\def\loop#1\repeat{\def\body{#1}\iterate}
\def\iterate{\body\let\next\iterate
  \else\let\next\relax\fi \next}
```

Therefore, the initial text is expanded into

```
\def\body{\ifnum\n>0 \printifprime
  \advance\p by2 }\iterate
```

Hence, the `\loop...\repeat` construct becomes

```
\ifnum\n>0 \printifprime\advance\p by2
           \let\next\iterate
\else \let\next\relax\fi \next
```

If `\n` > 0, this leads to

```
\printifprime ...
\let\next\iterate \next
```

and hence to

```
\testprimality ...
\let\next\iterate \next
```

and to

```
... \loop\trialdivision
    \ifunknown\advance\d by2 \repeat ...
\let\next\iterate \next
```

Now, `\iterate` will call `\body`, but the `\body` definition called will be the one defined by the second (inner) `\loop`, and chaos will follow! This explains why a group has been introduced. The group keeps the inner `\body` definition away from the outer `\loop` construct, hence each `\iterate` call produces the appropriate result.

Division trials

The last macro is where the actual division of \p by \d is made. An auxiliary variable \a is used.

```
\def\trialdivision{\a=\p \divide\a by\d
  \ifnum\a>\d \unknowntrue
  \else\unknownfalse\fi
  \multiply\a by\d
  \ifnum\a=\p \global\primefalse
              \unknownfalse\fi}
```

\p is copied into \a, then \a is divided by \d. This puts into \a the *integer part* of $\frac{\p}{\d}$. Two cases must then be considered:

1. if \a > \d, that is, if \d is smaller than the square root of \p, we are still in unknown territory. \d may be a divisor of \p, or there might be another divisor of \p larger than \d and smaller than the square root of \p root. The "unknown" boolean is therefore set to "true" with \unknowntrue.
2. if \a ≤ \d, we assume that we know, or at least, that we will know momentarily. We write therefore \unknownfalse.

In order to be sure, we must check if there is a remainder to \p's division by \d, or rather to \a's division by \d: \a is therefore multiplied by \d:

```
\multiply\a by\d
\ifnum\a=\p \global\primefalse
            \unknownfalse\fi
```

If \p is found again, it means that \d is one of \p's divisors. In that case, \p is of course not prime and the "prime" boolean is set to false with \primefalse. Since \trialdivision is actually located in the group surrounding the body of the \testprimality macro, and since the "prime" is needed outside \testprimality, the group must once again be transcended and the "prime" assignment must be forced to be global. Hence:

```
\global\primefalse
```

Finally, in the case where \d divides \p, we set \unknownfalse, which has the sole effect of causing the loop to end:

```
\loop\trialdivision
  \ifunknown\advance\d by2 \repeat
```

that is, no other divisor is tested. One can observe that there is no \global in front of \unknownfalse, because \ifunknown is used within and not outside the group.

If \p is not found again after the multiplication, it means that \d is not a divisor of \p. At that time, we had

- either \a ≤ \d, and therefore \a < \d (otherwise \p would have been found after the multiplication), and hence \unknownfalse, therefore the loop

```
\loop\trialdivision
  \ifunknown\advance\d by2 \repeat
```
stops and since this happens in the context
```
\d=3 \global\primetrue
\loop\trialdivision
  \ifunknown\advance\d by2 \repeat
```
where "`prime`" had been set to true, we conclude naturally that, no divisor having been found up to `\p`'s square root, `\p` is prime.
Therefore, at the end of `\testprimality`'s call, `\ifprime` succeeds and `\p` is printed.

- or `\a` > `\d`: in that case, we know nothing more, `\unknowntrue`, and the next divisor must be tried.

Conclusion

This ends the explanation of these macros, apart from a few subtleties which were not mentioned.

It takes TEX a lot of time to do complex operations such as the ones described. In order to execute`\primes{30}`, TEX spends more time than it needs on average to typeset a whole page with plain TEX. `\trialdivision` is expanded 132 times. With `\primes{1000}` there are 41331 expansions and with `\primes{10000}` there are 1441624 expansions.

It should be stressed that the previous macros are given in *The TEXbook* [1, pp. 218–219], with the following lines as the only explanation:

> The computation is fairly straightforward, except that it involves a loop inside a loop; therefore `\testprimality` introduces an extra set of braces, to keep the inner loop control from interfering with the outer loop. The braces make it necessary to say '`\global`' when `\ifprime` is being set true or false. TEX spent more time constructing that sentence than it usually spends on an entire page; the `\trialdivision` macro was expanded 132 times.

TEX's programming language is quite peculiar and we gave only a glimpse of it. The interested reader should dive into TEX's "bible", namely Donald Knuth's *TEXbook* [1].

The general format for constructing leaders is
`\leaders`⟨box or rule⟩`\hskip`⟨glue⟩ repeat box or rule
`\leaders`⟨box or rule⟩`\hfill` fill space with box or rule

TEX Fonts and Magnification

`\rm` Roman `\bf` **Bold** `\tt` `Typewriter`
`\sl` *Slant* `\it` *Italic* `\/` "italic correction"

`\magnification=`⟨number⟩	scale document by $n/1000$
`\magstep`⟨number⟩	scaling factor of $1.2^n \times 1000$
`\magstephalf`	scalling factor of $\sqrt{1.2}$
`\font\FN=`⟨fontname⟩	load a font, naming it `\FN`
`\font\FN=`⟨fontname⟩ `at` ⟨dimen⟩	load font scaled to dimension
`\font\FN=`⟨fontname⟩ `scaled` ⟨number⟩	load font scaled by $n/1000$
`true` ⟨dimen⟩	dimension with no scaling

Alignment Displays

`\settabs`⟨number⟩`\columns`	set equally spaced tabs
`\settabs\+`⟨sample line⟩`\cr`	set tabs as per sample line
`\+`⟨text$_1$⟩`&`⟨text$_2$⟩`&`$\cdots$`\cr`	tabbed text to be typeset
`\halign`	horizontal alignment
`\halign to`⟨dimen⟩	horizontal alignment
`\openup`⟨dimen⟩	add space between lines
`\noalign{`⟨vmode material⟩`}`	insert material after any `\cr`
`\tabskip=`⟨glue⟩	set glue at tab stops
`\omit`	omit the template for a column
`\span`	span two columns
`\multispan`⟨number⟩	span several columns
`\hidewidth`	ignore the width of an entry
`\crcr`	insert `\cr` if one is not present

Boxes

`\hbox to`⟨dimen⟩	hbox of given dimension
`\vbox to`⟨dimen⟩	vbox, bottom justified
`\vtop to`⟨dimen⟩	vbox, top justified
`\vcenter to`⟨dimen⟩	vbox, center justified (math only)
`\rlap`	right overlap material
`\llap`	left overlap material

Overfull Boxes

`\hfuzz`	allowable excess in hboxes
`\vfuzz`	allowable excess in vboxes
`\overfullrule`	width of overfull box marker. To eliminate entirely, set `\overfullrule=0pt`.

Indentation and Itemized Lists

`\indent`	indent
`\noindent`	do not indent
`\parindent=`⟨dimen⟩	set indentation of paragraphs
`\displayindent=`⟨dimen⟩	set indentation of math displays
`\leftskip=`⟨dimen⟩	skip space on left
`\rightskip=`⟨dimen⟩	skip space on right
`\narrower`	make paragraph narrower
`\item{`⟨label⟩`}`	singly indented itemized list
`\itemitem{`⟨label⟩`}`	doubly indented itemized list
`\hangindent=`⟨dimen⟩	hanging indentation for paragraph
`\hangafter=`⟨number⟩	start hanging indent after line n. If $n<0$, indent first $\lvert n\rvert$ lines.
`\parshape=`⟨number⟩	general paragraph shaping macro

Headers, Footers, and Page Numbers

`\nopagenumbers`	turn off page numbering
`\pageno`	current page number. To get roman nums, set `\pageno=`⟨negative number⟩
`\folio`	current page number, roman num if < 0
`\footline`	material to put at foot of page
`\headline`	material to put at top of page. To leave space, set `\voffset=2\baselineskip`, make room with `\advance\vsize by-\voffset`.

Macro Definitions

`\def\cs{`⟨replacement text⟩`}`	define the macro `\cs`
`\def\cs#1`$\cdots$`#`n{⟨repl. text⟩`}`	macro with parameters
`\let\cs=`⟨token⟩	give `\cs` token's current meaning

Advanced Macro Definition Commands

`\long\def`	macro whose args may include `\par`
`\outer\def`	macro not allowed inside definitions
`\global\def` or `\gdef`	definition that transcends grouping
`\edef`	expand while defining macro
`\xdef` or `\global\edef`	global version of `\edef`
`\noexpand`⟨token⟩	do not expand token
`\expandafter`⟨token⟩	expand item after token first
`\futurelet\cs`⟨tok$_1$⟩⟨tok$_2$⟩	equals `\let\cs=`⟨tok$_2$⟩⟨tok$_1$⟩⟨tok$_2$⟩
`\csname`. . . `\endcsname`	create a control sequence name
`\string\cs`	list characters in name, `\ c s`
`\number`⟨number⟩	list of characters in number
`\the`⟨internal quantity⟩	list of tokens giving value of quantity

Conditionals

The general format of a conditional is
`\if`⟨condition⟩⟨true text⟩`\else`⟨false text⟩`\fi`

`\ifnum`⟨num$_1$⟩⟨relation⟩⟨num$_2$⟩	compare two integers
`\ifdim`⟨dimen$_1$⟩⟨relation⟩⟨dimen$_2$⟩	compare two dimensions
`\ifodd`⟨num⟩	test for an odd integer
`\ifmmode`	test for math mode
`\if`⟨token$_1$⟩⟨token$_2$⟩	test if character codes agree
`\ifdim`	compare two dimensions
`\ifx`⟨token$_1$⟩⟨token$_2$⟩	test if tokens agree
`\ifeof`⟨number⟩	test for end of file
`\iftrue`, `\iffalse`	always true, always false
`\ifcase`⟨number⟩⟨text$_0$⟩`\or`⟨text$_1$⟩`\or`$\cdots$ `\or`⟨text$_n$⟩`\else`⟨text⟩`\fi`	choose text by ⟨number⟩
`\loop` α `\if`$\ldots\beta$ `\repeat`	loop $\alpha\beta\alpha\cdots\alpha$ until `\if` is false
`\newif\ifblob`	create a new conditional called `\ifblob`
`\blobtrue`, `\blobfalse`	set conditional `\ifblob` true, false

Dimensions, Spacing, and Glue

Dimensions are specified as ⟨number⟩⟨unit of measure⟩.
Glue is specified as ⟨dimen⟩ `plus`⟨dimen⟩ `minus`⟨dimen⟩.

point	`pt`	pica	`pc`	inch	`in`	centimeter	`cm`
m width	`em`	x height	`ex`	math unit	`mu`	millimeter	`mm`
1 pc = 12 pt		1 in = 72.72 pt		2.54 cm = 1 in		18 mu = 1 em	

Horizontal Spacing: `\quad` (skip 1em) `\qquad`
Horizontal Spacing (Text): `\thinspace` `\enspace` `\enskip` `\hskip`⟨glue⟩ `\hfil` `\hfill` `\hfilneg`
Horizontal Spacing (Math): thin space `\,` medium space `\>` thick space `\;` neg. thin space `\!` `\mskip`⟨muglue⟩

Vertical Spacing:	`\vskip`⟨glue⟩ `\vfil` `\vfill`
`\strut`	box w/ ht and depth of "(", zero width
`\phantom{`⟨text⟩`}`	invisible box with dim of ⟨text⟩
`\vphantom{`⟨text⟩`}`	box w/ ht & depth of ⟨text⟩, zero width
`\hphantom{`⟨text⟩`}`	box w/ width of ⟨text⟩, zero ht & depth
`\smash{`⟨text⟩`}`	typeset ⟨text⟩, set ht & depth to zero
`\raise`⟨dimen⟩`\hbox{`⟨text⟩`}`	raise box up
`\lower`⟨dimen⟩`\hbox{`⟨text⟩`}`	lower box down
`\moveleft`⟨dimen⟩`\vbox{`⟨text⟩`}`	move box left
`\moveright`⟨dimen⟩`\vbox{`⟨text⟩`}`	move box right
Skip Space Between Lines:	`\smallskip` `\medskip` `\bigskip`
encourage a break	`\smallbreak` `\medbreak` `\bigbreak`
break if no room	`\filbreak`
Set Line Spacing:	`\baselineskip =` ⟨glue⟩
single space	`\baselineskip = 12pt`
1 1/2 space	`\baselineskip = 18pt`
double space	`\baselineskip = 24pt`
Increase Line Spacing	`\openup`⟨dimen⟩
use `\jot`'s	`1\jot = 3pt`
Allow Unjustified Lines	`\raggedright`
Allow Unjustified Pages	`\raggedbottom`

Braces and Matrices

`\matrix`	rectangular array of entries
`\pmatrix`	matrix with parentheses
`\bordermatrix`	matrix with labels on top and left
`\overbrace`	overbrace, may be superscripted
`\underbrace`	underbrace, may be subscripted

For small matrices in text, use the following constructions:

`{a\,b \choose c\,d}` $\binom{a\ b}{c\ d}$
`\left( {a\atop c} {b\atop d} \right)` $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$

Displayed Equations

`\eqno`	equation number at right
`\leqno`	equation number at left
`\eqalign`	display several aligned equations
`\eqalignno`	display aligned equations numbered at right
`\leqalignno`	display aligned equations numbered at left
`\displaylines`	display several equations, centered
`\cases`	case by case definitions
`\noalign`	to insert space between lines in displays, use `\noalign{\vskip`⟨glue⟩`}` after any `\cr`
`\openup`⟨dimen⟩	add space between all lines in a display
